1. INTRODUCTION

1.1 Description

The TMS9918A/9928A/9929A video display processors (VDP) are N-channel MOS LSI devices used in video systems where data display on a raster-scanned home color television set or color monitor is desired. These devices generate all necessary video, control, and synchronization signals and also control the storage, retrieval, and refresh of display data in the dynamic screen refresh memory. The interfaces to the microprocessor, refresh memory, and the TV require a minimum of additional electronics for the TMS9918A.

In Section 1.4, there is a list of acronyms and a glossary of terms used in this manual.

The TMS9928A/9929A VDPs are functionally identical to the TMS9918A except that the NTSC color encoding circuitry has been removed and replaced with luminance and color difference signals. The TMS9918A is pin-for-pin compatible with the TMS9928A/9929A, except for three pins, the composite video output, the external video input and the CPU clock output. These pins are replaced with the Black/White luminance and composite sync (Y) output and two color difference pins, Blue (B-Y) and Red (R-Y) outputs, respectively. The color difference outputs allow the user to generate Red-Green-Blue (R-G-B) drive for direct color gun control, or composite video for use with NTSC or PAL video color monitor. However, to connect these three outputs to a R-G-B or monitor requires additional R-G-B or encoder circuitry.

The TMS9918A/9928A have a 525-line format for U.S. televisions while the TMS9929A has a 625-line format for use with the European PAL system.

The VDP has four video display modes: Graphics I, Graphics II, Multicolor and Text mode. The Text mode provides twenty-four 40-character rows in two colors and is intended to maximize the capacity of the TV screen to display alphanumeric character. The Multicolor mode provides an unrestricted 64×48 color-dot display employing 15 colors plus transparent. The Graphics I mode provides a 256×192 pixel display for generating pattern graphics in 15 colors plus transparent. The Graphics II mode is an enhancement of Graphics I mode, allowing it to generate more complex color and pattern displays. The four video display modes are described in detail in Section 2.4.

The video display consists of 35 planes: external VDP, backdrop, pattern plane, and 32 Sprite Planes. The planes are vertically stacked with the external VDP being the bottom or innermost plane. The backdrop plane is the next plane followed by the pattern plane that contains Graphics I and Graphics II patterns with the 32 Sprite Planes as the top planes.

The TMS9918A/9928A/9929A VDPs use either a 4K, 8K, or 16K-type low-cost dynamic memory (TMS4027, TMS4108, TMS4116) for storage of the display parameters.

The TMS9918A, TMS9928A, and TMS9929A interface identically to the host microprocessor making them software compatible. Thus, all references to VDP in this document apply to all three devices, except where noted.

1.2 FEATURES

- Single-chip solution for interfacing color TVs (excluding Random-Access Memory (RAM) and Radio Frequency (RF) modulator (TMS9918A only))
- 256×192 resolution on TV screen
- 15 unique colors plus transparent
- General 8-bit bidirectional interface to Central Processor Unit (CPU)
- Direct wiring to 4K, 8K, or 16K dynamic RAM memories
- Automatic and transparent refresh of dynamic RAMs
- Multiple VDP systems capability
- External VDP input capability (TMS9918A only)
- Composite video output (TMS9918A only)
- Unique planar representation for 3D simulation
- Standard 40-pin package
- Color difference outputs allow RGB drive — TMS9928A/9929A

1.3 TYPICAL APPLICATIONS

- Color computer terminals
- Home computers
- Drafting/design aids
- Teaching aids
- Industrial process monitoring
- Home educational systems
- Animation aids
- European 625-line TV (TMS9929A only)

The following example of a typical application may help introduce the user to the TMS9918A VDP. Figure 1-1 is a block diagram of a typical application. Each of the concepts presented in the example is described more fully in later sections of this manual.

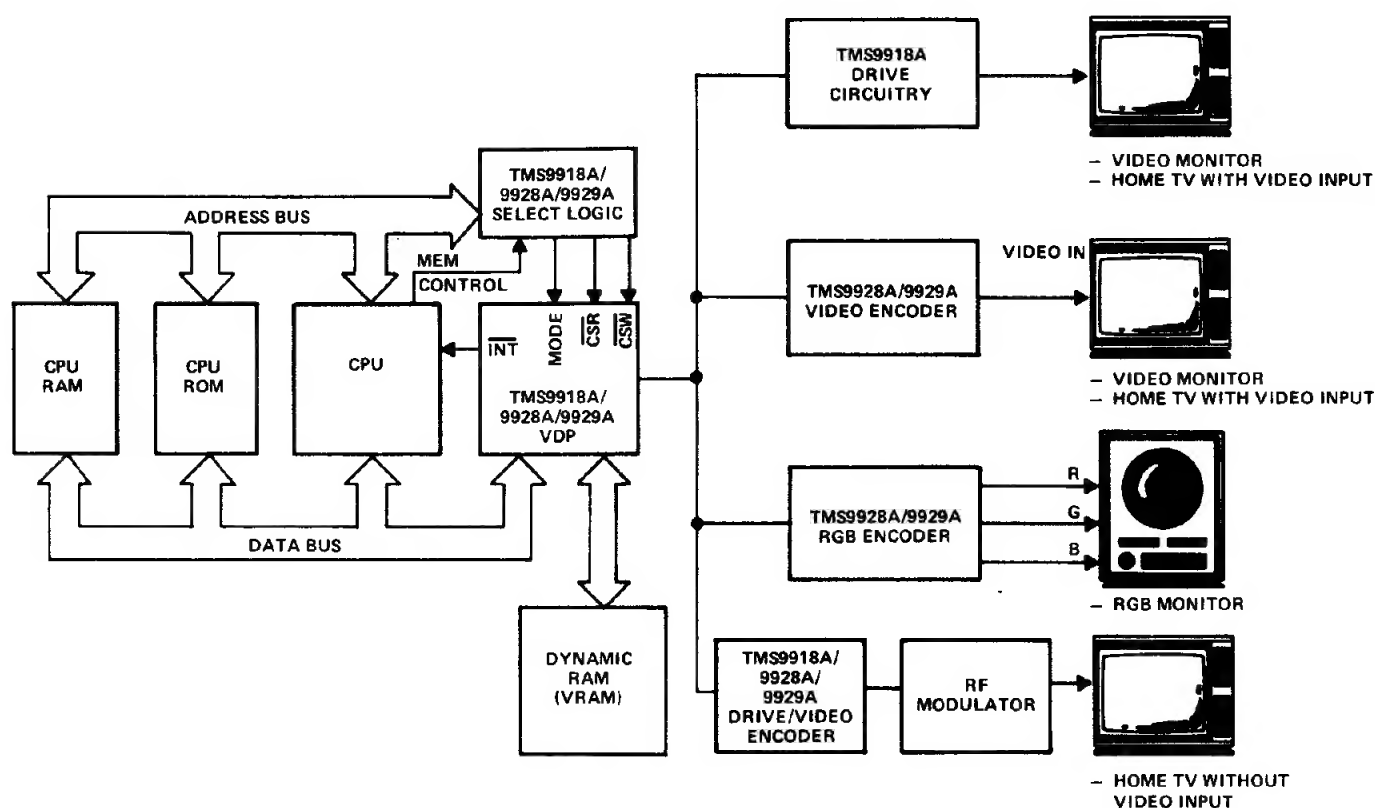

FIGURE 1-1 — SYSTEM BLOCK DIAGRAM

The VDP basically has three interfaces: CPU, color monitor, and dynamic refresh RAM (VRAM), the contents of which define the TV image. The TMS9918A also has eight write-only registers and a read-only status register.

The VDP communicates with the CPU via an 8-bit bidirectional data bus. Three control lines, decoded from the CPU address and enable lines, determine interpretation of the bus. Through the bus, the CPU can write to VRAM, read from VRAM, write to VDP registers, and read the VDP status. The VDP also generates an interrupt signal after every refresh of the TV display.

The dynamic RAM interface consists of direct wiring of eight $4K \times 1$, $8K \times 1$, or $16K \times 1$ dynamic RAS/CAS-type RAMs to the VDP. The amount of RAM required is dependent upon the features selected for use in the application.

The interface to the monitor can consist of either wiring the TMS9918A's composite video output pin (suitably buffered) to the input of a color or black-and-white monitor, or using an appropriate RF modulator to feed the signal into a TV antenna terminal. The TMS9928A/9929A require additional encoder circuitry to interface to a RGB or to a composite video monitor.

The VDP operates in four modes, and each one can affect the way the VRAM is mapped onto the television screen. In Graphics I and II modes, characters are mapped onto the screen in 8×8 pixel blocks, yielding 24 lines of 32 blocks (pattern positions) each. In Text mode, there are 24 lines of 40 blocks, each of which is 6×8 pixels. In Multicolor mode, there are 48 lines of 64 blocks, each of which is composed of 4×4 picture elements (pixels), all of one solid color. In addition to these, sprites can be superimposed onto the television image in Graphics I, II, and Multicolor mode. Furthermore, signals entering the TMS9918A through the external VDP input can be used as a background to the TMS9918A.

ACRONYMS AND GLOSSARY

B-Y	Blue color difference output
COMVID (Composite Video)	Contains luminance, chrominance and all sync pulse necessary for horizontal and vertical timing
CAS	Column Address Strobe
CPU	Central Processor Unit
CSR	CPU from VDP read select
CSW	CPU to VDP write select
CPUCLK	XTAL — 3
GROMCLK	XTAL — 24
LSB	Least Significant Bit
LSI	Large Scale Integration
MOS	Metal Oxide Semiconductor
MHz	Megahertz
MSB	Most Significant Bit
NTSC	National Television Standards Committee which specifies television signal standards for the USA
PAL	Phase Alternating Line
Pixel	Picture Element — the smallest point on the TV screen that can be independently controlled.
RAM	Random-Access Memory
RAS	Row-Address Strobe
RASTER	The area in which an image is reproduced
RF	Radio Frequency
R-G-B	Red-Green-Blue
ROM	Read-Only Memory
R/W	Read/Write
R-Y	Red color difference output
Sprite	An object whose pattern is relative to a specified X,Y coordinate and whose position can therefore be controlled by that coordinate with a positional resolution of one pixel
VDP	Video Display Processor
VRAM	Video RAM; refers to the dynamic RAMs that connect to the VDP and whose contents define the TV image
Y	Black/white luminance and composite sync

2. ARCHITECTURE

The TMS9918A video display processor (VDP) is designed to provide a simple interface between a microprocessor and a raster-scanned color television. The TMS9928A/9929A VDPs are designed as a simple interface between a microprocessor, and R-G-B monitor or video encoder which produces the video for a video monitor. Figure 2-1 is a block diagram of the major portions of the VDP architecture interfaces to the VDP, CPU, VRAM, and color television.

2.1 CPU INTERFACE

The VDP interface to the CPU using an 8-bit bidirectional data bus, three control lines, and an interrupt is shown in Figure 2-2. Through this interface the CPU can conduct four operations:

- (1) Write data bytes to VRAM
- (2) Read data bytes from VRAM
- (3) Write to one of the eight VDP write-only registers
- (4) Read the VDP Status Register.

Each of these operations requires one or more data transfers to take place over the CPU/VDP data bus interface. The interpretation of the data transfer is determined by the three control lines of the VDP.

NOTE

The CPU can communicate with the VDP simultaneously and asynchronously with the VDP's TV screen refresh operations. The VDP performs memory management and allows periodic intervals of CPU access to VRAM even in the middle of a raster scan.

2.1.1 CPU Interface Control Signals

The type and direction of data transfers are controlled by the CSW, CSR, and MODE inputs. CSW is the CPU to VDP write select. When it is active (low), the eight bits on CD0-CD7 are strobed into the VDP. CSR is the CPU from VDP read select. When it is active (low), the VDP outputs eight bits on CD0-CD7 to the CPU. CSW and CSR should never be simultaneously low at the same time. If both are low, the VDP outputs data on CD0-CD7 and latches in invalid data.

MODE determines the source or destination of a read or write data transfer. MODE is normally tied to a CPU low order address line (A14 for TMS9900).

2.1.2 CPU Write to VDP Register

The VDP has eight write-only registers and one read-only status register. The write-only registers control the VDP operation and determine the way in which VRAM is allocated. The status register contains interrupt, sprite coincidence and fifth sprite status flags.

Each of the eight VDP write-only registers can be loaded using two 8-bit data transfers from the CPU. Table 2-1 describes the required format for the two bytes. The first byte transferred is the data byte, and the second byte transferred controls the destination. The MSB of the second byte must be a 1. The next four bits are 0s, and the lowest three bits make up the destination register number. The MODE input is high for both byte transfers.

To rewrite the data in an internal register after a byte of data has already been loaded, the status register must be read so that internal CPU interface logic is reinitialized and will accept the next byte as data and not as a register destination. This situation may be encountered in interrupt-driven program environments. Whenever the status of VDP write parameters is in question, this procedure should be used.

NOTE

The CPU address is destroyed by writing to the VDP register.

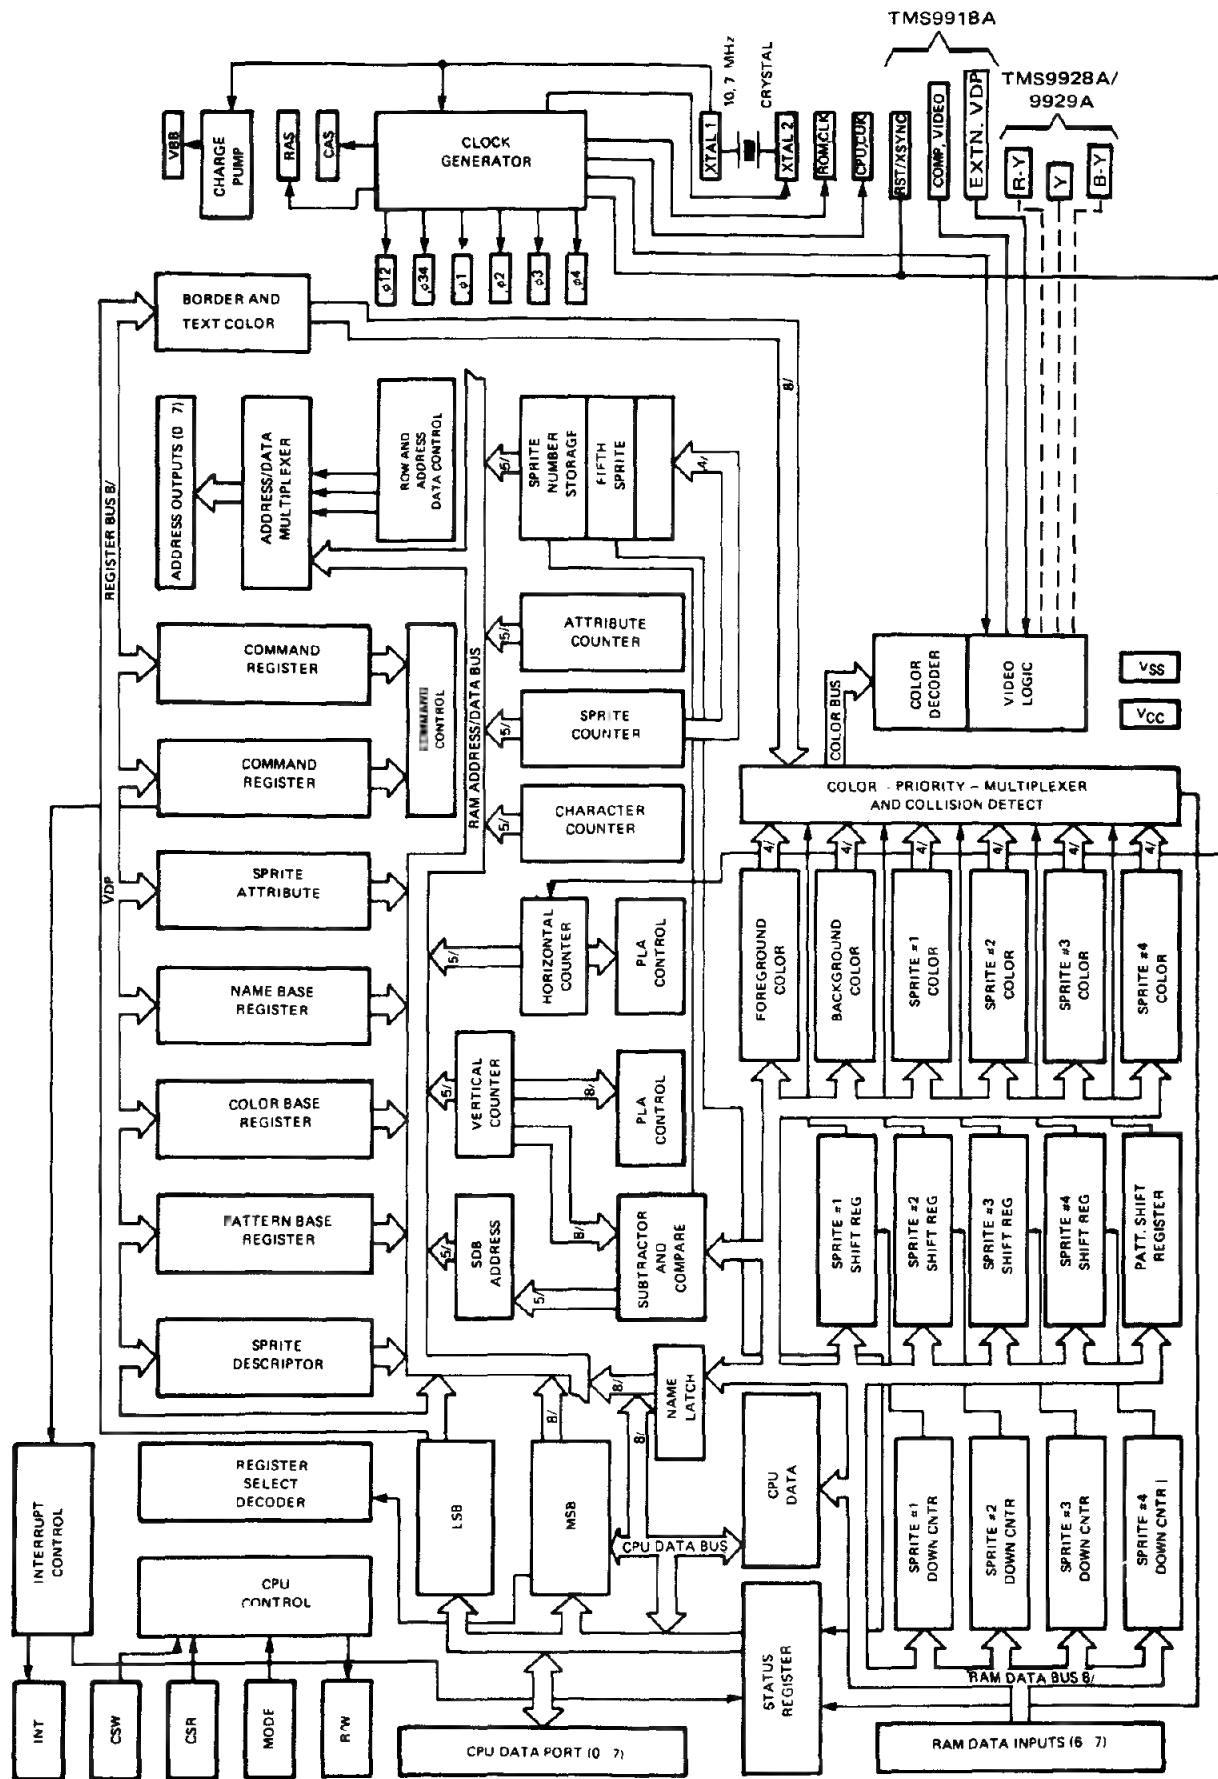

FIGURE 2-1 — VDP BLOCK DIAGRAM

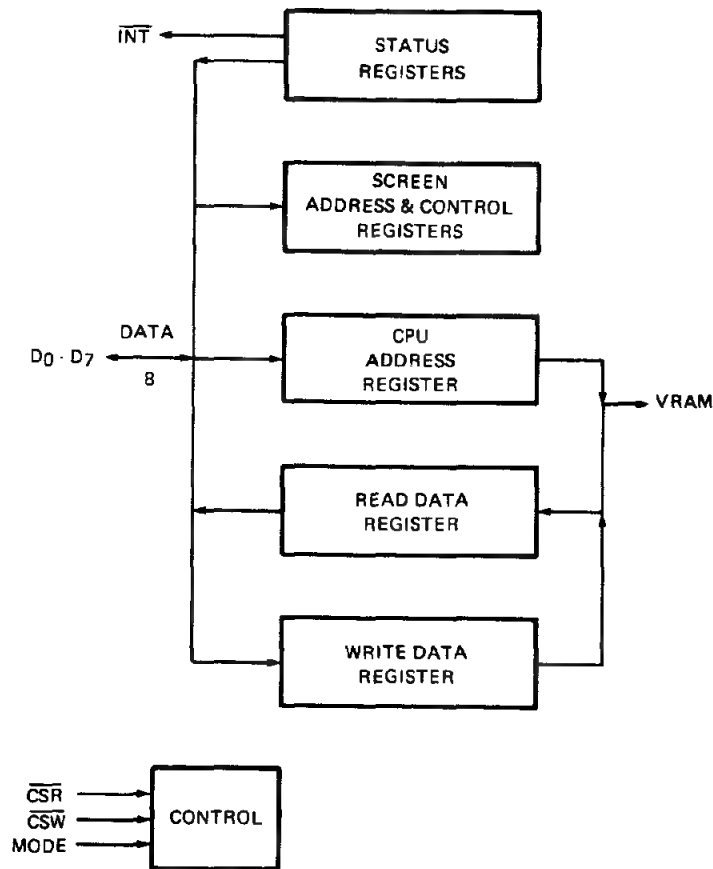

FIGURE 2-2 — VDP TO CPU INTERFACE

2.1.3 CPU Write to VRAM

The CPU transfers data to the VRAM through the VDP using a 14-bit autoincrementing address register. The address register setup requires 2-byte transfers. A 1-byte transfer is then required to write the data to the addressed VRAM byte. The address register is then autoincremented. Sequential VRAM writes require only 1-byte transfers since the address register is already set up. During setup of the address register, the two MSBs of the second address byte must be 0 and 1 respectively. **MODE** is high for both address transfers and low for the data transfer. **CSW** is used in all transfers to strobe the 8 bits into the VDP. See Table 2-1.

TABLE 2-1 — CPU/VDP DATA TRANSFERS

OPERATION	BIT								CSW	CSR	MODE
	0	1	2	3	4	5	6	7			
WRITE TO VDP REGISTER											
BYTE 1 DATA WRITE	D ₀	D ₁	D ₂	D ₃	D ₄	D ₅	D ₆	D ₇	0	1	1
BYTE 2 REGISTER SELECT	1	0	0	0	0	RS ₀	RS ₁	RS ₂	0	1	1
WRITE TO VRAM											
BYTE 1 ADDRESS SETUP	A ₆	A ₇	A ₈	A ₉	A ₁₀	A ₁₁	A ₁₂	A ₁₃	0	1	1
BYTE 2 ADDRESS SETUP	0	1	A ₀	A ₁	A ₂	A ₃	A ₄	A ₅	0	1	1
BYTE 3 DATA WRITE	D ₀	D ₁	D ₂	D ₃	D ₄	D ₅	D ₆	D ₇	0	1	0
READ FROM VDP REGISTER											
BYTE 1 DATA READ	D ₀	D ₁	D ₂	D ₃	D ₄	D ₅	D ₆	D ₇	1	0	1
READ FROM VRAM											
BYTE 1 ADDRESS SETUP	A ₆	A ₇	A ₈	A ₉	A ₁₀	A ₁₁	A ₁₂	A ₁₃	0	1	1
BYTE 2 ADDRESS SETUP	0	0	A ₀	A ₁	A ₂	A ₃	A ₄	A ₅	0	1	1
BYTE 3 DATA READ	D ₀	D ₁	D ₂	D ₃	D ₄	D ₅	D ₆	D ₇	1	0	0

2.1.4 CPU Read from VDP Status Register

The CPU can read the contents of the status register with a single-byte transfer. MODE is high for the transfer. CSR is used to signal the VDP that a read operation is required.

2.1.5 CPU Read from VRAM

The CPU reads from the VRAM through the VDP using the autoincrementing address register. A 1-byte transfer is then required to read the data from the addressed VRAM byte. The address register is then autoincremented. Sequential VRAM data reads require only a 1-byte transfer since the address register is already set up. During setup of the address register, the two MSBs of the second address byte must be 0. By setting up the address this way, a read cycle to VRAM is initiated and read data will be available for the first data transfer to the CPU. (See Table 2-1). MODE is high for the address byte transfers and low for the data transfers. The VDP requires approximately 8 microseconds to fetch the VRAM byte following the last data transfer and 2 microseconds following address setup.

The CPU interacts with VRAM memory through the VDP. The amount of time necessary for the CPU to transfer a byte of data to or from VRAM memory can vary from 2 to 8 microseconds. Once the VDP has been told to read or write a byte of data to or from VRAM it takes approximately 2 microseconds until the VDP is ready to make the data transfer. In addition to this 2 microsecond delay, the VDP must wait for a CPU access window; i.e., the period of time when the VDP is not occupied with memory refresh or screen display and is available to read or write data.

The worst case time between windows occurs during the Graphics I or Graphics II mode when sprites are being used. During the active display, CPU windows occur once every 16 memory cycles giving a maximum delay of 6 microseconds (a memory cycle takes about 372 nanoseconds). In the Text mode the CPU windows occur at least once out of every three memory cycles or a worst case delay of about 1.1 microseconds. Finally, in the Multicolor mode, CPU windows occur at least once out of every four memory cycles.

If the user needs to access memory in 2 microseconds, two situations occur where the time waiting for an access window is effectively zero. Both of these are independent of the display mode being used.

The first situation occurs when the blank bit of register 1 is 0. With this bit low, the entire screen will show only border color and the VDP does not have to wait for a CPU access window at any time.

The second situation occurs when the VDP is in the vertical refresh mode. The VDP issues an interrupt output at the end of each active area. This signal indicates that the VDP is entering the vertical refresh mode and that for the next 4.3 milliseconds there is no waiting for an access window. If the user wants the CPU to access memory during this interval, it is necessary for the controlling CPU to monitor the interrupt output of the VDP (the CPU can either poll this output or use it as an interrupt input).

The program that monitors the interrupt output must allow for its own delays in responding to the interrupt signal and recognize how much time it has left during the 4300 microsecond refresh period. The CPU must write a 1 to the interrupt enable bit of Register 1 in order to enable the interrupt for each frame, and then read the status register each time an interrupt is issued to clear the interrupt output. A summary of these delay times is presented in Table 2-2.

TABLE 2-2 — MEMORY ACCESS DELAY TIMES

CONDITION	MODE	VDP DELAY	TIME WAITING FOR AN ACCESS WINDOW	TOTAL TIME
Active Display Area	Text	2 μ s	0 - 1.1 μ s	2 - 3.1 μ s
Active Display Area	Graphics I, II	2 μ s	0 - 5.95 μ s	2 - 8 μ s
4300 μ s after Vertical Interrupt Signal	All	2 μ s	0 μ s	2 μ s
Register I Blank Bit 0	All	2 μ s	0 μ s	2 μ s
Active Display Area	Multicolor	2 μ s	0 - 1.5 μ s	2 - 3.5 μ s

2.1.6 VDP Interrupt

The VDP INT output pin is used to generate an interrupt at the end of each active-display scan, which is about every 1/60 second for the TMS9918A/9928A and 1/50 second for the TMS9929A. The INT output is active when the Interrupt Enable bit (IE) in VDP Register 1 is a 1 and the F bit of the status register is a 1. Interrupts are cleared when the status register is read.

2.1.7 VDP Initialization

The VDP is externally initialized whenever the RESET input is active (low) and must be held low for a minimum of 3 microseconds. The external reset synchronizes all clocks with its falling edge, sets the horizontal and vertical counters to known states, and clears VDP registers 0 and 1. The video display is automatically blanked since the BLANK bit in VDP register 1 becomes a 0. The VDP, however, continues to refresh the VRAM even though the display is blanked. While the RESET line is active, the VDP does not refresh the VRAM.

2.2 WRITE-ONLY REGISTERS

The eight VDP write-only registers are shown in Figure 2-3. They are loaded by the CPU as described in Section 2.1.2. Registers 0 and 1 contain flags to enable or disable various VDP features and modes. Registers 2 through 6 contain values that specify starting locations of various sub-blocks of VRAM. The definitions of these sub-blocks are described in Section 2.4. Register 7 is used to define backdrop and text colors.

Each register is described in the following paragraphs.

2.2.1 Register 0

Register 0 contains two VDP option control bits. All other bits are reserved for future use and must be 0s.

BIT 6 M3 (mode bit 3) (see Section 2.3.2 for table and description)

BIT 7 External VDP enable/disable

0 disables external VDP input

1 enables external VDP input

NOTE

Enabling bit 7 in the TMS9928A/9929A causes A-Y and B-Y to go to the sync level only when all planes in front of the pixel under question are transparent.

2.2.2 Register 1 (contains 8 VDP option control bits)

BIT 0 4/16K selection

0 selects 4027 RAM operation

1 selects 4108/4116 RAM operation

BIT 1 BLANK enable/disable

0 causes the active display area to blank

1 enables the active display

Blanking causes the display to show border color only

BIT 2 IE (Interrupt Enable)

0 disables VDP interrupt

1 enables VDP interrupt

BIT 3,4 M1, M2 (mode bits 1 and 2)

M1, M2 and M3 determine the operating mode of the VDP:

M1	M2	M3	
0	0	0	Graphics I mode
0	0	1	Graphics II mode
0	1	0	Multicolor Mode
1	0	0	Text mode

BIT 5 Reserved

- BIT 6 Size (sprite size select)
- 0 selects Size 0 sprites (8 × 8 bit)
- 1 selects Size 1 sprites (16 × 16 bits)
- BIT 7 MAG (Magnification option for sprites)
- 0 selects MAG0 sprites (1X)
- 1 selects MAG1 sprites (2X)

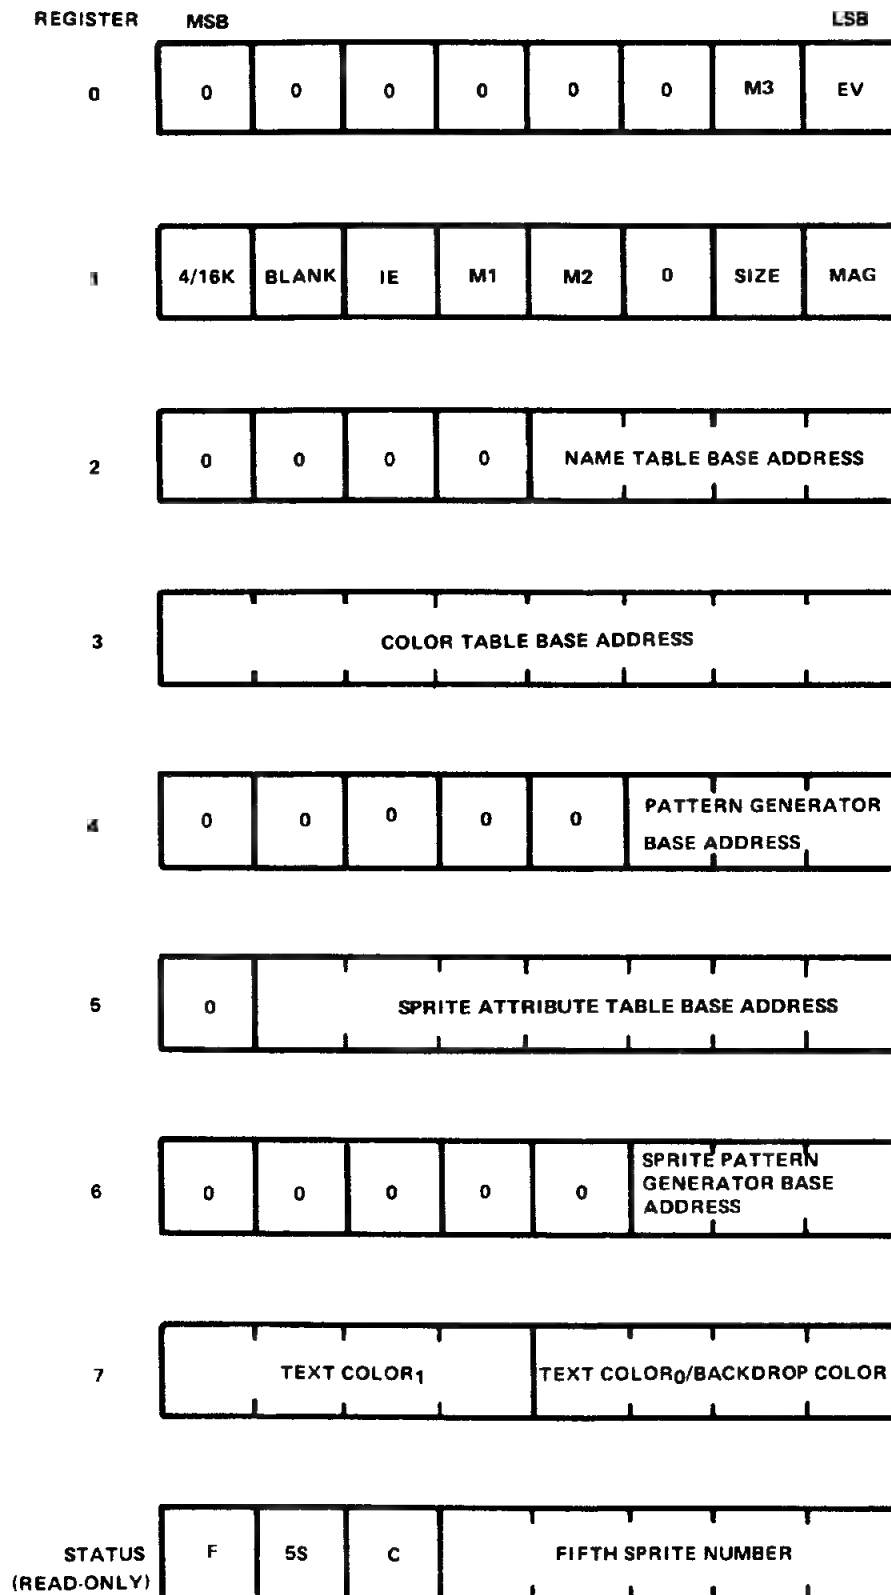

FIGURE 2-3 – VDP REGISTERS

2.2.3 Register 2

Register 2 defines the base address of the Name Table sub-block. The range of its contents is from 0 to 15. The contents of the register form the upper 4 bits of the 14-bit Name Table addresses; thus the Name Table base address is equal to (Register 2) *400(hex).

2.2.4 Register 3

Register 3 defines the base address of the Color Table sub-block. The range of its contents is from 0 to 255. The contents of the register form the upper 8 bits of the 14-bit Color Table addresses; thus the Color Table base address is equal to (Register 3) *40(hex).

2.2.5 Register 4

Register 4 defines the base address of the Pattern, Text or Multicolor Generator sub-block. The range of its contents is 0 through 7. The contents of the register form the upper 3 bits of the 14-bit Generator addresses; thus the Generator base address is equal to (Register 4) *800(hex).

2.2.6 Register 5

Register 5 defines the base address of the Sprite Attribute Table sub-block. The range of its contents is from 0 through 127. The contents of the register form the upper 7 bits of the 14-bit Sprite Attribute Table addresses; thus the base address is equal to (Register 5) *80(hex).

2.2.7 Register 6

Register 6 defines the base address of the Sprite Pattern Generator sub-block. The range of its contents is 0 through 7. The contents of the register form the upper 3 bits of the 14-bit Sprite Pattern Generator addresses; thus the Sprite Pattern Generator base address is equal to (Register 6) *800(hex).

2.2.8 Register 7

The upper 4 bits of Register 7 contain the color code of color 1 in the Text mode. The lower 4 bits contain the color code for color 0 in the Text mode and the backdrop color in all modes.

2.2.9 Setup Values for VDP Registers 2 through 6.

VRAM TABLE ADDRESSING

Register 2 in the VDP contains the starting address for the Name Table sub-block.

$$R2 * 400_{(16)} = \text{START ADDRESS}$$

2.3 STATUS REGISTER

The VDP has a single 8-bit status register that can be accessed by the CPU. The status register contains the interrupt pending flag, the sprite coincidence flag, the fifth sprite flag, and the fifth sprite number, if one exists. The format of the status register is shown in Figure 2-3 and is discussed in the following paragraphs.

The status register may be read at any time to test the F, C, and 5S status bits. Reading the status register will clear the interrupt flag, F. However, asynchronous reads will cause the frame flag (F) bit to be reset and therefore missed. Consequently, the status register should be read only when the VDP interrupt is pending.

2.3.1 Interrupt Flag (F)

The F status flag in the status register is set to 1 at the end of the raster scan of the last line of the active display. It is reset to a 0 after the status register is read or when the VDP is externally reset. If the Interrupt Enable bit in VDP Register 1 is active (1), the VDP interrupt output (INT) will be active (low) whenever the F status flag is a 1.

Note that the status register needs to be read frame by frame in order to clear the interrupt and receive the new interrupt of the next frame.

2.3.2 Coincidence Flag (C)

The C status flag in the status register is set to a 1 if two or more sprites coincide. Coincidence occurs if any two sprites on the screen have one overlapping pixel. Transparent colored sprites, as well as those that are partially or completely off the screen, are also considered. Sprites beyond the Sprite Attribute Table terminator (D016) are not considered. The C flag is cleared to a 0 after the status register is read or the VDP is externally reset. The status register should be read immediately upon powerup to ensure that the coincidence flag is reset.

The VDP checks each pixel position for coincidence during the generation of the pixel regardless of where it is located on the screen. This occurs every 1/60th of a second for the TMS9918A and TMS9928A and every 1/50th of a second for the TMS9929A. Thus, when moving sprites more than one pixel position during these intervals, it is possible for the sprites to have multiple pixels overlapping or even to have passed completely over one another when the VDP checks for coincidence.

2.3.3 Fifth Sprite Flag (5S) and Number

The 5S status flag in the status register is set to a 1 whenever there are five or more sprites on a horizontal line (lines 0 to 192) and the frame flag is equal to a 0. The 5S status flag is cleared to a 0 after the status register is read or the VDP is externally reset. The number of the fifth sprite is placed into the lower 5 bits of the status register when the 5S flag is set and is valid whenever the 5S flag is 1. The setting of the fifth sprite flag will not cause an interrupt.

2.4 VIDEO DISPLAY MODES

The VDP displays an image on the screen that can best be envisioned as a set of display planes sandwiched together. Figure 2-4 shows the definition of each of the planes. Objects on planes closest to the viewer have higher priority. In cases where two entities on two different planes are occupying the same spot on the screen, the entity on the higher priority plane will show at that point. For an entity on a specific plane to show through, all planes in front of that plane must be transparent at that point. The first 32 planes (Figure 2-5) each may contain a single sprite. The areas of the Sprite Planes, outside of the sprite itself, are transparent. Since the coordinates of the sprite are in terms of pixels, the sprite can be positioned and moved about very accurately. Sprites are available in three sizes: 8×8 pixels, 16×16 pixels, and 32×32 pixels.

Behind the Sprite Planes is the Pattern Plane. The Pattern Plane is used for textual and graphics images generated by the Text, Graphics I, Graphics II, or Multicolor modes. Behind the Pattern Plane is the backdrop, which is larger in area than the other planes so that it forms a border around the other planes. The last and lowest priority plane is the External VDP Plane. Its image is defined by the external VDP input pin which allows the TMS9918A to mix the external video signal internal to the chip.

This mixing must occur outside of the chip for the TMS9928A and TMS9929A. This is achieved through the color difference outputs swinging to a special level (sync level is shown in Figure 2-6) not used by the color difference signals in normal operation. This occurs when bit 7 of Register 0 is set high. External mixing circuitry is required to detect this change in the level of the color difference signals and then switch from the VDP signals to an external source's signals (see Figures 2-7 and 2-8).

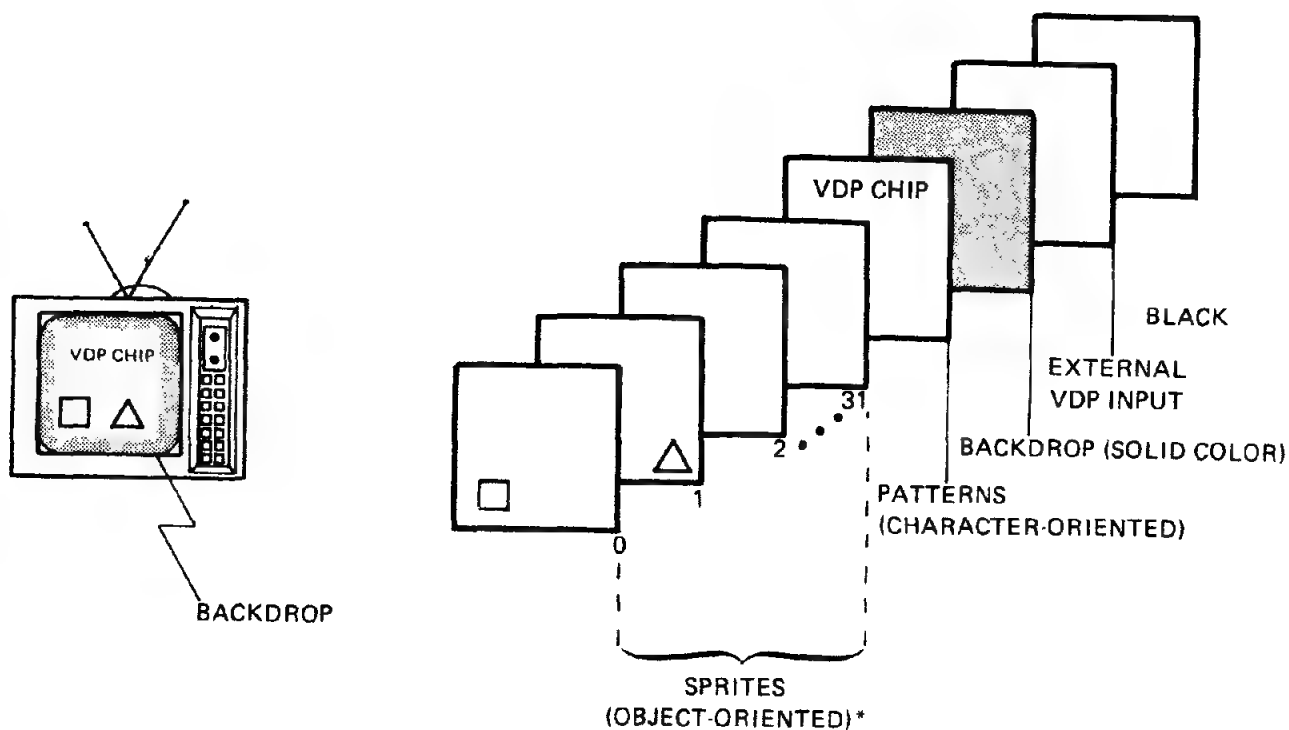

FIGURE 2-4 — VDP DISPLAY PLANES (DEFINITION)

FIGURE 2-5 — VDP DISPLAY PLANES (FIRST 32 PLANES)

FIGURE 2-6 — TMS9928A/9929A SIGNAL WAVEFORMS FOR MULTIPLE VDP OPERATION

FIGURE 2-7 — USING COLOR DIFFERENCE SIGNALS TO MIX EXTERNAL COLOR DIFFERENCE TYPE SOURCE

FIGURE 2-8 — USING COLOR DIFFERENCE SIGNALS TO MIX EXTERNAL VIDEO SOURCES

The backdrop consists of a single color used for the display borders and as the default color for the active display area. The default color is stored in the VDP Register 7. When the backdrop color register contains the transparent code, the backdrop automatically defaults to black if the external VDP mode is not selected.

The 32 Sprite Planes are used for the 32 sprites in the Multicolor and Graphics modes. They are not used in the Text mode and are automatically transparent. Each of the sprites can cover an 8×8 , 16×16 , or 32×32 pixel area on its plane. Any part of the plane not covered by the sprite is transparent. All or part of each sprite may also be transparent. Sprite 0 is on the outside or highest plane, and sprite 31 is on the plane immediately adjacent to Pattern Plane. Whenever a pixel in a Sprite Plane is transparent, the color of the next plane can be seen through that plane. If, however, the sprite pixel is non-transparent, the colors of the lower planes are automatically replaced by the sprite color.

There is also a restriction on the number of sprites on a line. Only four sprites can be active on any horizontal line. Additional sprites on a line will be automatically made transparent for that line. Only those sprites that are active on the display will cause the coincidence flag to set. The VDP status register provides a flag bit and the number of the fifth sprite whenever this occurs. The Pattern Plane is used in the Text, Multicolor, and Graphics modes for display of the graphic patterns of characters. Whenever a pixel on the Pattern Plane is nontransparent, the backdrop color is automatically replaced by the Pattern Plane color. When a pixel in the Pattern Plane is transparent, the backdrop color can be seen through the Pattern Plane.

The VDP has four video color display modes that appear on the Pattern Plane: Graphics I mode, Graphics II mode, Text mode, and Multicolor mode. Graphics I and Graphics II modes cause the Pattern Plane to be broken up into groups of 8×8 pixels, called pattern positions. Since the full image is 256×192 pixels, there are 32×24 pattern positions on the screen in the Graphics modes.

In Graphics I mode, 256 possible patterns may be defined for the 768 pattern positions with two unique colors allowed for each line of a pattern definition. Thus, all 15 colors plus transparent may be used in a single pattern position.

In Text mode, the Pattern Plane is broken into groups of 6×8 pixels, called text positions. There are 40×24 text positions on the screen in this mode. In Text mode, sprites do not appear on the screen and two colors are defined for the entire screen by VDP Register 7.

In Multicolor mode, the screen is broken into a grid of 64×48 positions, each of which is a 4×4 pixel. Within each position, one unique color is allowed.

The VDP registers define the base addresses for several sub-blocks within VRAM. These sub-blocks form tables which are used to produce the desired image on the TV screen. The Sprite Pattern Generator Table and the Sprite Attribute Table are used to form sprites. The contents of these tables must all be provided by the microprocessor. Animation is achieved by altering the contents of VRAM in real time.

The VDP can display the 15 colors shown in Table 2-3. The VDP colors also provide eight different gray levels for displays on monochrome television; the luminance value in the table indicates these levels, 0.00 being black and 1.00 being white. All other values in the table are expressed as percentages of the white/black voltage swing.

NOTE

The gray levels differ slightly for the TMS9918A when compared to the TMS9928A/9929A.

Whenever all planes are of the transparent color at a given point, and external video is not selected, the color shown at that point will be black.

TABLE 2-3 -- COLOR ASSIGNMENTS

-	LEVEL	-	-	0.00	-.46	-.46

2.4.1 Graphics I Mode

The VDP is in Graphics I mode when M1, M2, and M3 bits in VDP registers 1 and 0 are zero. When in this mode the Pattern Plane is divided into a grid of 32 columns by 24 rows of pattern positions as shown in Figure 2-9). Each of the pattern positions contains 8×8 pixel. The tables in VRAM used to generate the Pattern Plane are the Pattern Generator, Name, and Color Tables which require 2848 VRAM bytes. Figure 2-9 illustrates the mapping of these tables into the Pattern Plane. Less memory is required if all 256 possible pattern definitions are not required. The tables can be overlapped to reduce the amount of VRAM needed for pattern generation. Examples of VRAM memory allocation are provided in Section 3.3.

FIGURE 2-9 -- PATTERN GRAPHICS NAME TABLE MAPPING

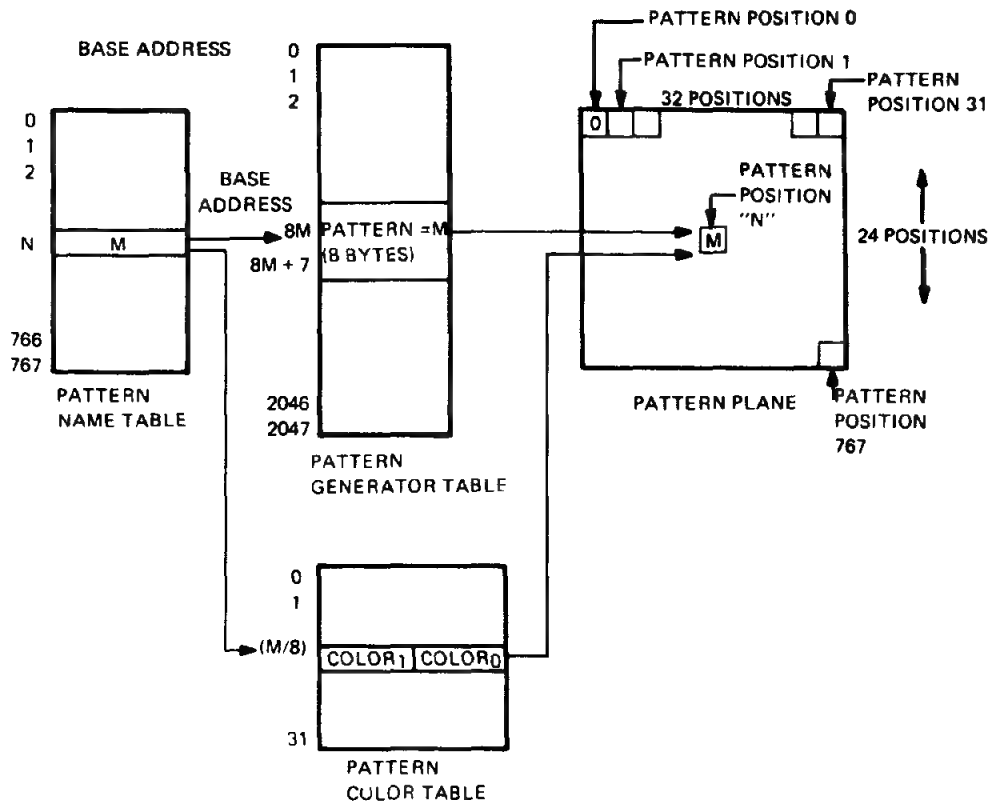

FIGURE 2-10 — GRAPHICS I MODE MAPPING

The Pattern Generator Table contains a library of patterns that can be displayed in the pattern positions. It is 2048 bytes long and is arranged into 256 patterns, each of which is 8 bytes long, yielding 8×8 bits. All of the 1s in the 8-byte pattern can designate one color (color 1), while all the 0s can designate another color (color 0).

The full 8-bit pattern name is used to select one of the 256 pattern definitions in the Pattern Generator Table. The table is a 2048-byte block in VRAM beginning on a 2-kilobyte boundary. The starting address of the table is determined by the generator base address in VDP Register 4. The base address forms the three MSBs of the 14-bit VRAM address for each Pattern Generator Table entry. The next 8 bits indicate the 8-bit name of the selected pattern definition. The lowest 3 bits of the VRAM address indicate the row number within the pattern definition.

There are 8 bytes required for each of the 256 possible unique 8×8 pattern definitions. The first byte defines the first row of the pattern, and the second byte defines the second row. The first bit of each of the eight bytes defines the first column of the pattern. The remaining rows and columns are similarly defined. Each bit entry in the pattern definition selects one of the two colors for that pattern. A 1 bit selects the color code (color 1) contained in the most significant 4 bits of the corresponding color table byte. A 0 bit selects the other color code (color 0). An example of pattern definition mapping is provided in Figure 2-11.

ROW/BYTE	COLUMN (PATTERN)						BIT (PATTERN DEFINITION)							
	0	1	2	3	4	5	0	1	2	3	4	5	6	7
0		C	C	C	C	C	0	1	1	1	1	1	0	0
1						C	0	0	0	0	0	1	0	0
2						C	0	0	0	0	0	1	0	0
3			C	C	C	C	0	0	1	1	1	1	0	0
4						C	0	0	0	0	0	1	0	0
5						C	0	0	0	0	0	1	0	0
6		C	C	C	C	C	0	1	1	1	1	1	0	0
7							0	0	0	0	0	0	0	0

NOTES: VDP register 7 entry: 71₁₆.
 Color code 7 is cyan (signified above by 'C').
 Color code 1 is black (signified above by a space).
 Bit 0 is the most significant bit of each data byte.

FIGURE 2-11 — PATTERN DISPLAY MAPPING

The color of the 1s and 0s is defined by the Pattern Color Table that contains 32 entries, each of which is 1 byte long. Each entry defines two colors: the most significant 4 bits of each entry define the color of the 1s, and the least significant 4 bits define the color of the 0s. The first entry in the color table defines the colors for patterns 0 to 7; the next entry for patterns 8 to 15, and so on. (See Table 2-4 for assignments.) Thus, 32 different pairs of colors may be displayed simultaneously.

The Pattern Name Table is located in a contiguous 768-byte block in VRAM beginning on a 1-kilobyte boundary. The starting address of the Name Table is determined by the 4-bit Name Table base address field in VDP Register 2. The base address forms the upper 4 bits of the 14-bit VRAM address. The lower 10 bits of the VRAM address are formed from the row and column counters. An example of pattern name table addressing is given in Section 3.3.

TABLE 2-4 — GRAPHICS I MODE COLOR TABLE

Byte No.	Pattern No.	Byte No.	Pattern No.
0	0..7	16	128..135

Each byte entry in the Name Table is either the name of or the pointer to a pattern definition in the Pattern Generator Table. The upper 5 bits of the 8-bit name identify the color group of the pattern. There are 32 groups of 8 patterns. The same two colors are used for all eight patterns in a group; the color codes are stored in the VDP Color Table. The Color Table is located in a 32-byte block in VRAM beginning on a 64-byte boundary. The table starting address is determined by the 8-bit Color Table base address in VDP Register 3. The base address forms the upper 8 bits of the 14-bit Color Table entry VRAM address. The next bit is a 0 and the lowest 5 bits are equal to the upper 5 bits of the corresponding Name Table entries.

Since the tables in VRAM have their base addresses defined by the VDP registers, a complete switch of the values in the tables can be made by simply changing the values in the VDP registers. This is especially useful when one wishes to time-slice between two or more screens of graphics.

When the Pattern Generator Table is loaded with a pattern set, manipulation of the Pattern Name Table contents can change the appearance of the screen. Alternatively, a dynamically changing set of patterns throughout the course of a graphics session is easily accomplished since all tables are in VRAM. A total of 2848 VRAM bytes are required for the Pattern, Name, Color and Generator tables. Less memory is needed if all 256 possible pattern definitions are not required; the tables can be overlapped to reduce the amount of VRAM needed for pattern generation. Examples of VRAM memory allocation are provided in Section 3.3.

2.4.2 Graphics II Mode

The VDP is in the Graphics II mode bits ($M1 = 0$, $M2 = 0$ and $M3 = 1$). The Graphics II mode is similar to Graphics I mode except it allows a larger library of patterns so that a unique pattern generator entry may be made for each of the 768 (32×24) pattern positions on the video screen. Additionally, more color information is included in each 8×8 graphics pattern. Thus, two unique colors may be specified for each byte of the 8×8 pattern. A larger amount of VRAM (12 kilobytes) is required to implement the full usage of the Graphics II mode.

Like Graphics I mode, the Graphics II mode Pattern Name Table contains 768 entries which correspond to the 768 pattern positions on the display screen. Because the Graphics I mode pattern names are only 8 bits in length, a maximum of 256 pattern definitions may be addressed using the addressing scheme discussed in Section 2.4.10. Graphics II mode, however, segments the display screen into three equal parts of 256 pattern positions each and also segments the Pattern

Generator Table into three equal blocks of 2048 bytes each. Pattern definitions in the first third of the display screen correspond to pattern positions in the upper third. Likewise, pattern definitions in the second and third blocks of the Pattern Generator Table correspond to the second and third areas of the Pattern Plane.

The Pattern Name Table is also segmented into three blocks of 256 names each so that names found in the upper third reference pattern definitions are found in the upper 2048 bytes in Pattern Generator Table. Similarly, the second and third blocks reference pattern definitions in the second 2048-byte block and third-2048 byte block, respectively. Thus, if 768 patterns are uniquely specified, an 8-bit pattern name will be used three times, once in each segment of the Pattern Name Table. The Pattern Generator Table falls on 8-kilobyte boundaries and may be located in the upper or lower half of 16K memory based on the MSB of the pattern generator base in VDP Register 4. The LSBs must be set to all 1s.

The Color Table is also 6144 bytes long and is segmented into three equal blocks of 2048 bytes. Each entry in the Pattern Color Table is 8 bytes which provides the capability to uniquely specify color 1 and color 0 for each of the 8 bytes of the corresponding pattern definition. The addressing scheme is exactly like that of the Pattern Generator Table except for the location of the table in VRAM. This is controlled by the loading of the MSB of the color base in VDP Register 3. The LSBs must be set to all 1s.

Figure 2-12 illustrates the Graphics II mode mapping scheme. Note that pattern names, P1, P2, and P3, correspond to pattern generator entries in the three blocks of the Pattern Generator Table. Note also how these three names map to the display screen. Figure 2-13 is an example of a Pattern Generator and Pattern Color Table entry.

FIGURE 2-13 — PATTERN DISPLAY MAPPING

2.4.3 Multicolor Mode

The VDP is in Multicolor mode when mode bits $M1 = 0$, $M2 = 1$, and $M3 = 0$. Multicolor mode provides an unrestricted 64×48 color square display. Each color square contains a 4×4 block of pixels. The color of each of the color squares can be any one of the 15 video display colors plus transparent. Consequently, all 15 colors can be used simultaneously in the Multicolor mode. The Backdrop and Sprite Planes are still active in the Multicolor mode.

The Multicolor Name Table is the same as that for the graphics modes, consisting of 768 name entries, although the name no longer points to a color list. Color is now derived from the Pattern Generator Table. The name points to an 8-byte segment of VRAM in the Pattern Generator Table.

Only 2 bytes of the 8-byte segment are used to specify the screen image. These 2 bytes specify four colors, each color occupying a 4×4 -pixel area. The 4 MSBs of the first byte define the color of the upper left quarter of the multicolor pattern; the LSBs define the color of the upper right quarter. The second byte similarly defines the lower left and right quarters of the multicolor pattern. The 2 bytes thus map into an 8×8 -pixel multicolor pattern. (See Figure 2-14).

FIGURE 2-14 — MULTICOLOR LIST MAPPING

The location of the 2 bytes within the 8-byte segment pointed to by the name is dependent upon the screen position where the name is mapped. For names in the top row (names 0-31), the 2 bytes are the first two within the groups of 8-byte segments pointed to by the names. The next row of names (32-63) uses the bytes 3 and 4 within the 8-byte segments. The next row of names uses bytes 5 and 6 while the last row of names uses bytes 7 and 8. This series repeats for the remainder of the screen.

For example, referring to Figure 2-15 if Name Table entry 0 (pattern position 0) multicolor block #N (name = N), the multicolor pattern displayed will be an 8 × 8-pixel block consisting of colors A, B, C, and D which comprise the first two bytes of the Multicolor Table. If, however, name #N is located in Name Table entry 33, (Pattern position 33), the colors displayed will be colors E, F, G, and H as specified by bytes 3 and 4 of the multicolor block pointed to by the name.

Likewise, pattern positions which lie in rows 2 and 3 would cause colors I, J, K, L and colors M, N, O, P, respectively, to be displayed. Thus, it can be seen that the color displayed from the multicolor generator block is dependent upon pattern position on the screen. Figure 2-16 illustrates the Multicolor mode mapping scheme.

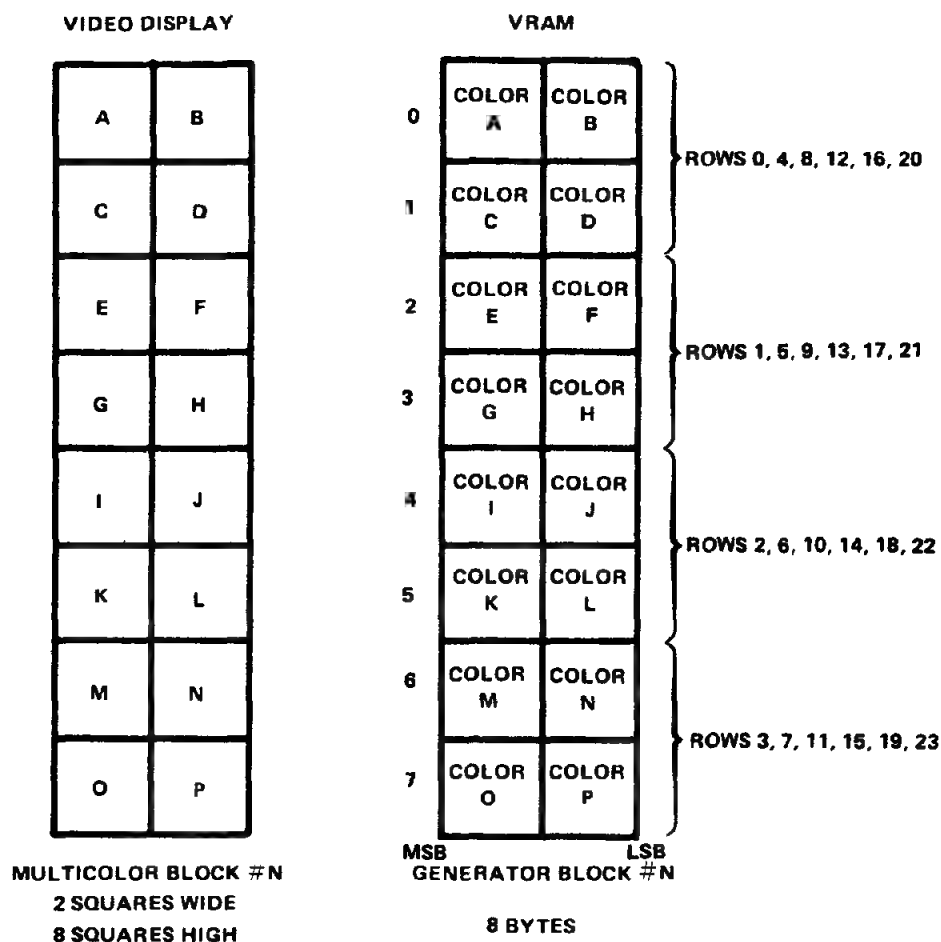

FIGURE 2-15 — MULTICOLOR BLOCK DISPLAY

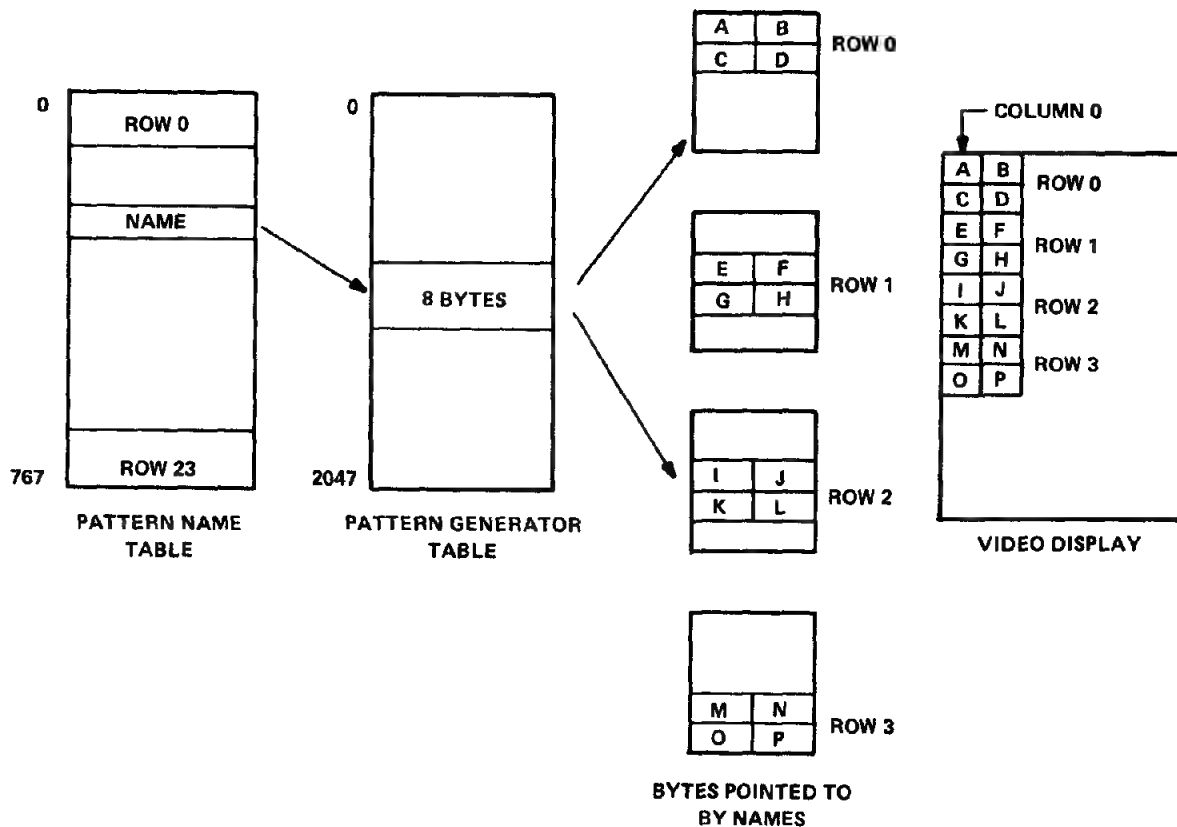

FIGURE 2-16 — MULTICOLOR MODE MAPPING

The mapping of VRAM contents to screen image is simplified by using duplicate names in the Name Table since the series of bytes used within the 8-byte segment specifies a 2×8 color square pattern on the screen as a straightforward translation from the 8-byte segment in VRAM pointed to by the common name.

When used in this manner, 768 bytes are still used for the Name Table and 1536 bytes are used for the color information in the Pattern Generator Table (24 rows \times 32 columns \times 8 bytes/pattern position). Thus, a total of 1728 bytes in VRAM are required. It should be noted that the tables begin on even 1K and 2K boundaries and are therefore not contiguous. An example of multicolor VRAM memory allocation is given in Section 3.3.

2.4.4 Text Mode

The VDP is in Text mode when mode bits M1 = 1, M2 = 0, and M3 = 0. In this mode, the screen is divided into a grid of 40 text positions across and 24 down. (See Figure 2-17). Each of the text positions contains 6 pixels across and 8 pixels down. The tables used to generate the Pattern Plane are the Pattern Name Table and the Pattern Generator Table. There can be up to 256 unique patterns defined at any time. The pattern definitions are stored in the Pattern Generator Table in VRAM and can be dynamically changed. The VRAM contains a Pattern Name Table which maps the pattern definition into each of the 960 pattern cells on the Pattern Plane (Figure 2-18). Sprites are not available in Text mode.

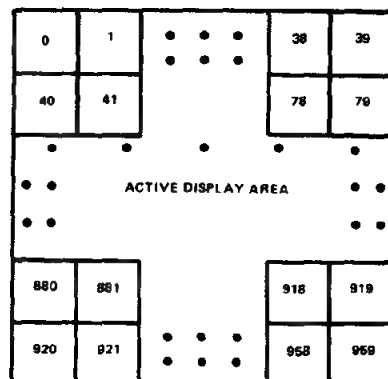

FIGURE 2-17 — TEXT MODE NAME TABLE PATTERN POSITIONS

As with the Graphics modes, the Pattern Generator Table contains a library of text patterns that can be displayed in the text positions. It is 2048 bytes long and is arranged in 256 text patterns, each of which is 8 bytes long. Since each text position on the screen is only 6 pixels across, the least significant 2 bits of each text pattern are ignored, yielding 6×8 bits in each text pattern. Each 8-byte block defines a text pattern in which all the 1s in the text pattern take on one color when displayed on the screen, while all the 0s take on another color. These colors are chosen by loading VDP Register 7 with the color 1 and color 0 in the left and right nibbles, respectively (see Section 2.2).

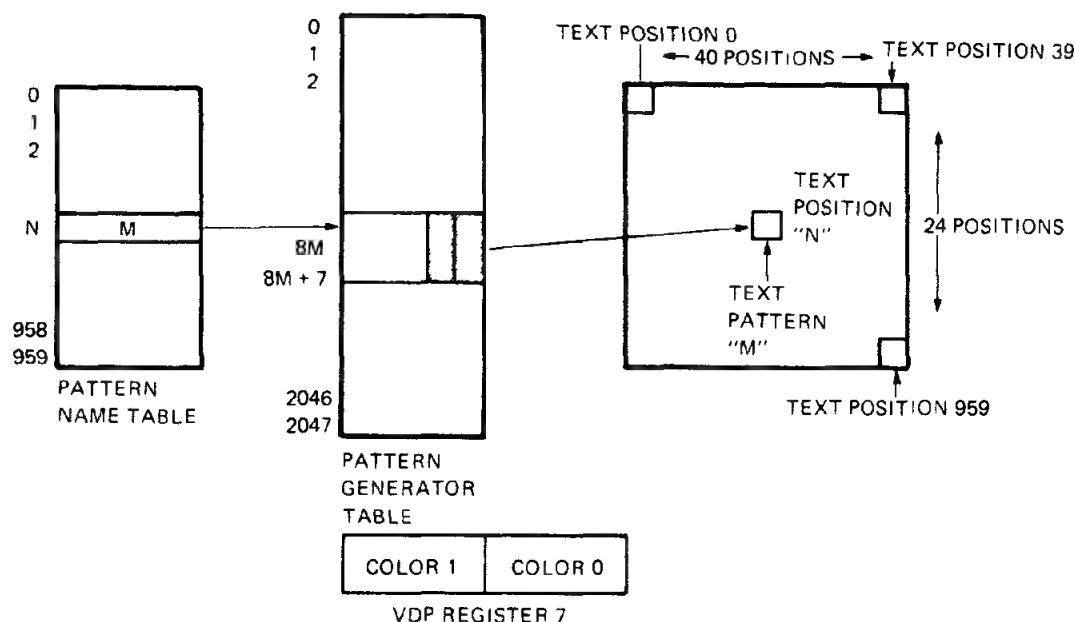

FIGURE 2-18 — MAPPING OF VRAM INTO THE PATTERN PLANE IN TEXT MODE

In the Text mode, the Pattern Name Table determines the position of the text pattern on the screen as shown in Figure 2-18. There are 960 entries in the Pattern Name Table, each 1 byte long. There is a one-to-one correspondence between text pattern positions on the screen and entries in the Pattern Name Table ($40 \times 24 = 960$). The first 40 entries correspond to the top row of text pattern positions on the screen, the next 40 to the second row, and so on. The value of an entry in the Pattern Name Table indicates which of the 256 text patterns is to be placed at that spot on the Pattern plane.

The Pattern Name Table is located in a contiguous 960-byte block in VRAM, beginning on a 1-kilobyte boundary. The starting address of the name table is determined by the 4-bit name table base address field in VDP Register 2. The base address forms the upper 4 bits of the 14-bit VRAM address. The lower 10 bits of the VRAM address point to 1 of 960 pattern cells. The name table is organized by rows. An example of Pattern Name Table addressing is given in Section 4.

Each byte entry in the name table is the pointer to a pattern definition in the Pattern Generator Table. The same two colors are used for all 256 patterns; the color codes are stored in VDP Register 7.

As the name implies, the Text mode is intended mainly for textual applications, especially those in which the 32 patterns-per-line in Graphics modes is insufficient. The advantage is that eight more patterns can be fitted onto one line; the disadvantages are that sprites cannot be used, and only two colors are available for the entire screen.

With care, the same text pattern set that is used in Text mode can be also used in Graphics I mode. This is done by ensuring that the least significant 2 bits of all the character patterns are 0. Thus, a switch from Text mode to Pattern mode results in a stretching of the space between characters, and a reduction of the number of characters per line from 40 to 32. As with the Graphics Modes, once a character set has been defined and placed into the Pattern Generator, updating the Pattern Name Table will produce and manipulate textual material on the screen.

The full 8-bit pattern name is used to select 1 of the 256 pattern definitions in the pattern generator table. The table is a 2048-byte block in VRAM, beginning on a 2-kilobyte boundary. The starting address of the table is determined by the generator base address in VDP Register 4. The base address forms the 3 MSBs of the 14-bit VRAM address for each Pattern Generator Table entry. The next 8 bits are equal to the 8-bit name of the selected pattern definition. The lowest 3 bits of the VRAM address are equal to the row number within the pattern definition.

There are 8 bytes required for each of the 256 possible unique 6×8 pattern definitions. The first byte defines the first row of the pattern, and the second byte defines the second row. The least significant 2 bits in each byte are not used. However, it is strongly recommended that these bits be 0s. Each bit entry in the pattern definition selects one of the two colors for

that pattern. A 1 bit selects the color code (color 1) contained in the most significant 4 bits of VDP Register 7. A 0 bit selects the other color code (color 0) which is in the least significant 4 bits of the same VDP Register. Figure 2-18 is an example of pattern definition mapping.

A total of 3008 VRAM bytes are required for the Pattern Name Generator Tables. Less memory is required if all 256 possible pattern definitions are not required; the tables can be overlapped to reduce the amount of VRAM needed for pattern generation. Examples of VRAM memory allocation are provided in Section 3.3.

2.4.5 Sprites

The video display can have up to 32 sprites on the highest priority video planes. The sprites are special animation patterns which provide smooth motion and multilevel pattern overlaying. The location of a sprite is defined by the top left-hand corner of the sprite pattern. The sprite can be easily moved pixel-by-pixel by redefining the sprite origin. This provides a simple but powerful method of quickly and smoothly moving special patterns. The sprites are not active in the Text mode. The 32 Sprite Planes are fully transparent outside of the sprite itself.

The sub-blocks in VRAM that define sprites are the Sprite Attribute Table (see Figure 2-19) and the Sprite Generator Table (see Section 4.4). These tables are similar to their equivalents in the pattern realm in that the Sprite Attribute Table specifies where the sprite goes on the screen, while the Sprite Generator Table describes what the sprite looks like. Sprite Pattern formats are given in Table 2-5.

FIGURE 2-19 — SPRITE ATTRIBUTE TABLE ENTRY

TABLE 2-5 — SPRITE PATTERN FORMATS

SIZE	MAG	AREA	RESOLUTION	BYTES/PATTERN
0	0	8 × 8	single pixel	8
1	0	16 × 16	single pixel	32
0	1	16 × 16	2 × 2 pixels	8
1	1	32 × 32	2 × 2 pixels	32

Figure 2-20 illustrates the manner in which the VRAM tables map into the existence of sprites on the display. Since there are 32 sprites available for display, there are 32 entries in the Sprite Attribute Table. Each entry consists of four bytes. The entries are ordered so that the first entry corresponds to the sprite on the sprite 0 plane, the next to the sprite on the sprite 1 plane, and so on. The Sprite Attribute Table is $4 \times 32 = 128$ and is located in a contiguous 128-byte block in VRAM, beginning on a 128-byte boundary.

The starting address of the table is determined by the 7-bit Sprite Attribute Table base address in VDP Register 5. The base address forms the upper 7 bits of the 14-bit VRAM address. The next 5 bits of the VRAM address are equal to the sprite number. The lowest 2 bits select 1 of the 4 bytes in Sprite 2 Attribute Table entry for each sprite. Each table entry contains 4 bytes which specify the sprite position, sprite pattern name, and color, as shown in Figure 2-19.

FIGURE 2-20 — SPRITE MAPPING

The first two bytes of each entry of the Sprite Attribute Table determine the position of the sprite on the display. The first byte indicates the vertical distance of the sprite from the top of the screen, in pixels. It is defined such that a value of -1 puts the sprite butted up at the top of the screen, touching the backdrop area. The second byte describes the horizontal displacement of the sprite from the left edge of the display. A value of 0 butts the sprite up against the left edge of the backdrop. Note that all measurements are taken from the upper left pixel of the sprite.

When the first two bytes of an entry position a sprite so it overlaps backdrop, the part of the sprite that is within the backdrop is displayed normally. The part of the sprite that overlaps the backdrop is hidden from view by the backdrop. This allows the animator to move a sprite into display from behind the backdrop.

The displacement in the first byte is partially signed, in that values for vertical displacement between -31 and 0 (E116 to 0) allow a sprite to bleed-in from the top edge of the backdrop. Similarly, horizontal displacement values in the vicinity of 255 allow a sprite to bleed-in from the right side of the screen. To allow sprites to bleed-in from the left edge of the backdrop, a special bit in the third byte of the Sprite Attribute Table entry is used.

Byte 3 of the Sprite Attribute Table entry contains the pointer to the Sprite Generator Table that specifies what the sprite should look like. This is an 8-bit pointer to the sprite patterns definition, the Sprite Generator Table. The sprite name is similar to that in the Graphics Modes.

Byte 4 of the Sprite Attribute Table entry contains the color of the sprite in its lower 4 bits (see Table 2-3 for color assignments). The MSB is the Early Clock (EC) bit. When set to 0, this bit does nothing. When set to 1, the horizontal position of the sprite is shifted to the left by 32 pixels. This allows a sprite to bleed-in from the left edge of the backdrop. Values for horizontal displacement (byte 2 in the entry) in the range 0 to 32 cause the sprite to overlap with the left-hand border of the backdrop.

The Sprite Generator Table is a maximum of 2048 bytes long beginning on the 2-kilobyte boundaries. It is arranged into 256 blocks of 8 bytes each. The third byte of the Sprite Attribute Table entry, then specifies which 8-byte block to use to specify a sprite's shape. The 1s in the Sprite Generator cause the sprite to be defined at the point; 0s cause the transparent color to be used. The starting address of the table is determined by the sprite generator base address in VDP Register 6. The base address forms the 3 MSB of the 14-bit VRAM address. The next 8 bits of the address are equal to sprite name, and the last 3 bits are equal to the row number within the sprite pattern. The address formation is slightly modified for $SIZE_1$ sprites.

There is a maximum limit of four sprites that can be displayed on one horizontal line. If this rule is violated, the four highest-priority sprites on the line are displayed normally. The fifth and subsequent sprites are not displayed on that line. Furthermore, the fifth-sprite bit in the VDP status register is set to a 1, and the number of the violating fifth sprite is loaded into the status register (see Section 2.3).

Larger sprites than 8×8 pixels can be used if desired. The MAG and SIZE bits in VDP register 1 are used to select the various options described in the following paragraphs.

MAG = 0, SIZE = 0:	No options chosen
MAG = 1, SIZE = 0	The Sprite Generator Table uses 8 bytes to describe the sprite; however, each bit in the Sprite Generator maps into 2×2 pixels on the TV screen, effectively doubling the size of the sprite to 16×16 .
MAG = 0, SIZE = 1:	The Sprite Generator Table uses 31 bytes to define the sprite shape; the result is a 16×16 -pixel sprite. The mapping of the 32 bytes into the sprite image is as shown in Figure 2-21. Mapping is still 1 bit to 1 pixel.
MAG = 1, SIZE = 1:	Same as MAG = 0, SIZE = 1 except each bit now maps into a 2×2 -pixel area, yielding a 32×32 sprite.

The VDP provides sprite coincidence checking. The coincidence status flag in the VDP status register is set to a 1 whenever two active sprites have 1 bits at the same screen location.

Sprite processing is terminated if the VDP finds a value of 208 (D016) in the vertical position field of any entry in the Sprite Attribute Table. This permits the Sprite Attribute Table to be shortened to the minimum size required; it also permits the user to blank out part or all of the sprites by simply changing one byte in VRAM.

A total of 2176 VRAM bytes are required for the Sprite Name and Pattern Generator Tables. Significantly less memory is required if all 256 possible sprite pattern definitions are not required. The Sprite Attribute Table can also be shortened as described in the preceding paragraph. The tables can be overlapped to reduce the amount of VRAM required for sprite generation. Examples of VRAM memory allocation are provided in Section 3.3.

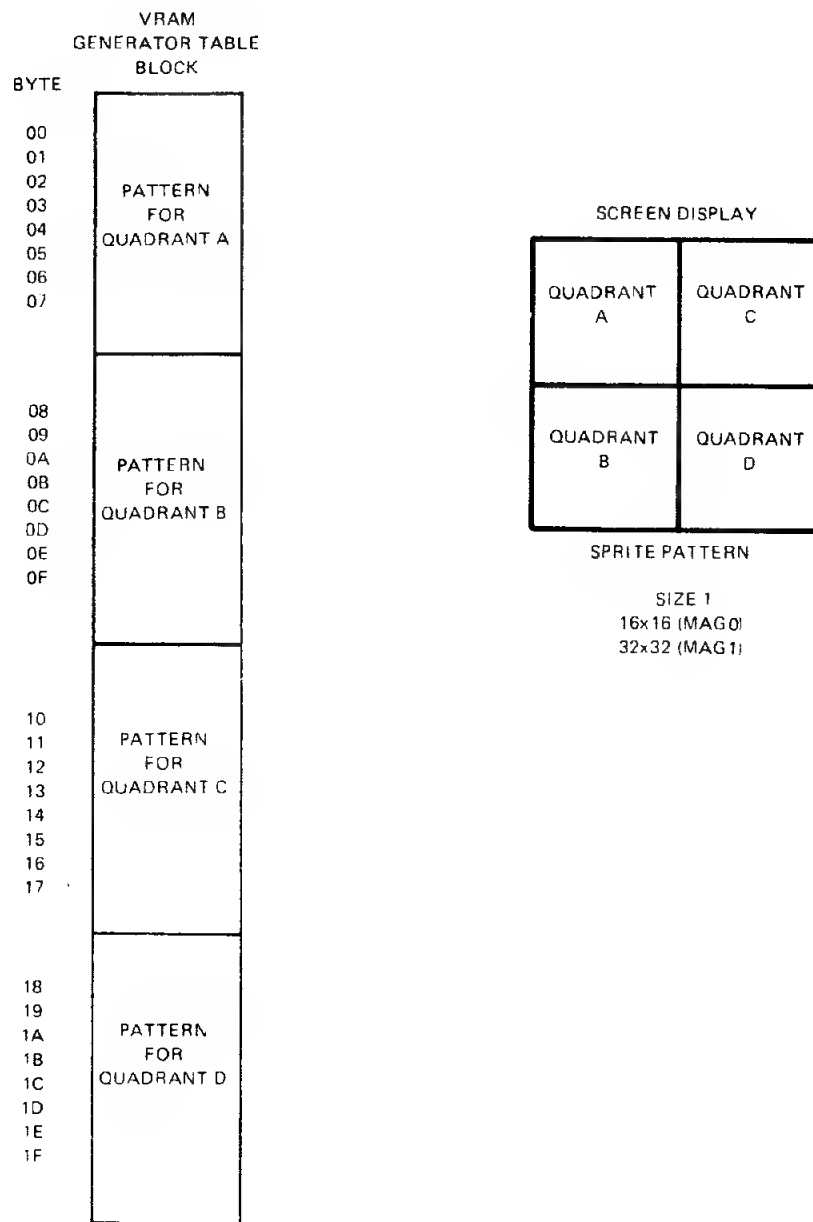

FIGURE 2-21 — SIZE 1 SPRITE MAPPING

2.4.6 A Step-by-Step Approach to Create Patterns and Sprites

PATTERNS

1. Use an 8×8 pattern similar to that in Figure A. Each small square represents one pixel on the screen.

FIGURE A

2. Fill in the blocks to create your text character or graphics pattern. Examples of the letter A and an ARROW are shown in Figures B and C.

FIGURE B

FIGURE C

NOTE

If these patterns are to be used in the Text mode, (40 patterns per line), the pattern should be inside a left-justified 6×8 block like the A shown in Figure B. If all of the Text patterns are inside this 6×8 block, they can be used for Text and Graphics 1 and 2 modes.

3. Assign 1s to the filled-in areas and 0s to the blanks. Then convert the 1s and 0s to their hexadecimal equivalents, as shown in Figure D.

FIGURE D

4. Now place the eight bytes defining the pattern into the Pattern Generator Table. Assume the Pattern Generator Table sub-block is located at 800_{16} and the arrow pattern is to be named 00_{16} . Then place the eight pattern bytes as follows:

800		}	PATTERN NAME 00
801	00		
802	04		
803	06		
804	FF		
805	06		
806	04		
807	00		
808		}	PATTERN NAME 01
809			
80A			
80B			
80C			
80D			
80E			
80F			
810			
//			
900	00	}	PATTERN NAME 20
901	00		
902	00		
903	00		
904	00		
905	00		
906	00		
907	00		
908			
//			
A08	20	}	PATTERN NAME 41
A09	50		
A0A	88		
A0B	88		
A0C	F8		
A0D	88		
A0E	88		

NOTE

When using text in your applications, you can place the eight bytes of the text character in its ASCII number location.

Example: ASCII SPACE = 20_{16}

$$7 - 3F_{16}$$

A - 41¹⁶₁₆

$$B = 42_{16}^{16}$$

C = 43₁₆

Etc.

This simplifies writing text to the screen. Simply write the ASCII name directly to the Pattern Name Table.

A space character is shown in Pattern Generator Table position 20, and A is shown in pattern name 41.

SPRITES

1. Determine whether to use 8×8 or 16×16 sprite patterns. Then use the appropriate work pattern, as shown in Figures E and F.

FIGURE E

FIGURE F

2. Fill in the blocks to create your sprite pattern. Examples are shown in Figures G and H.

FIGURE G

FIGURE H

3. Next encode the sprite patterns as in the Pattern Section. The 8×8 sprite encodes exactly as the 8×8 pattern, but the 16×16 sprite encodes as shown in Figure J.

FIGURE I

FIGURE J

Break the 16×16 block pattern into four 8×8 patterns. Next, encode the 8×8 patterns starting in the upper left corner, then do the lower left, upper right, and lower right.

4. Place the 8 bytes for 8×8 sprites or 32 bytes for 16×16 sprites in the Sprite Generator Table. Assuming the sprite generator table is located at location 0000, Figures K and L show how the tables should look for 8×8 and 16×16 sprites.

3. VDP INTERFACES AND OPERATION

3.1 VDP/VRAM INTERFACE

The VDP can access up to 16,384 bytes of VRAM using a 14-bit VRAM address. The VDP fetches data from the VRAM in order to process the video image described later. The VDP also stores data in or reads in data from the VRAM during a CPU-VRAM data transfer. The VDP automatically refreshes the VRAM.

3.1.1 VRAM Interface Control Signals

The VDP-VRAM interface consists of two 8-bit data buses (RD0-RD7 unidirectional, AD0-AD7 bidirectional) and three control lines, as shown in Figure 3-1. The VRAM outputs data to the VDP on the VRAM read data bus (RD0-RD7). The VDP outputs both the address and data to the VRAM over the VRAM address/data bus (AD0-AD7). The VRAM row address is output when \overline{RAS} is active (low). The column address is output when \overline{CAS} is active (low). Data is output to the VRAM when $\overline{R/W}$ is active (low).

3.1.2 VRAM Memory Types

The VDP can use 4027-type 4K, 4108-type 8K, or 4116-type 16K dynamic RAMs. The 4/16K bit in VDP register 1 is a 0 for 4027-type RAMs and a 1 for 4108- and 4116-type RAMs. There is a minor difference between the way 4027s and 4108s/4116s are wired to the VDP. In the 4027, all \overline{CE} pins are tied to ground. In the 4108/4116 the A6 lines on the 4116 and 4108 (the same pin as \overline{CE} on 4027's) are all tied to AD1 on the TMS9918A. A jumper can be used to select the VRAM type.

3.1.3 VDP to DRAM Address Connections

The VDP can be easily connected to either the 4027 or 4116 DRAMs. However, due to different pin numbering standards, it is possible to connect the VDP to the DRAMs incorrectly. Table 3-1 shows the recommended way to connect a VDP to either DRAM. Other DRAMs, such as the single +5 V supply type, can also be used by following the 4K or 16K columns in Table 3-1.

TABLE 3-1 — VDP TO DRAM ADDRESS CONNECTIONS

VDP	4116 or 16K	4027 or 4K
AD0	DATA ONLY	DATA ONLY
AD1	A6	DATA ONLY
AD2	A5	A5
AD3	A4	A4
AD4	A3	A3
AD5	A2	A2
AD6	A1	A1
AD7	A0	A0

When connecting the data ports together, ensure that corresponding RAMs (assuming 8 by 1 DRAMs) are properly connected to the corresponding input or output of the VDP. For example, AD0 of the corresponding input or output D input of the RAM, and RD0 of the VDP should connect to the Q output of the same RAM. The same is true for all AD and RD corresponding pins for each of the eight DRAMs.

NOTE

CD0 is the MSB of the CD bus; CD7 is the LSB.

AD0 is the MSB of the AD bus; AD7 is the LSB.

RD0 is the MSB of the RD bus; RD7 is the LSB.

RAMs have the reverse convention.

AD7 is the MSB of the AD bus, and AD0 is the LSB.

Therefore, AD7 of the VDP connects to AD of the 4116, and AD1 connects to A6. Data coming into the VDP on CD0 goes to VRAM on AD0 and returns to the VDP on RD0.

FIGURE 3-1 – VRAM INTERFACE

3.2 VRAM MEMORY ADDRESS DERIVATION

Table 3-2 summarizes the VRAM address derivation for all VDP modes of operation. Section 4 of this manual contains examples of how typical VRAM addresses are computed by the VDP.

TABLE 3-2 — PATTERN GRAPHICS ADDRESS LOCATION TABLES

GRAPHICS I MODE ADDRESS LOCATION

The TMS9918A/9928A operates at 262 lines per frame and approximately 60 frames per second in a noninterlaced mode of operation. The TMS9929A operates at 313 lines per frame and approximately 50 frames per second in a noninterlaced mode of operation.

3.3 VRAM ADDRESSING EXAMPLE

A typical application might require up to 256 unique 8×8 patterns with no more than 2 colors per pattern and up to 32 8×8 sprites.

These conditions dictate in which mode the VDP is to be used. The sprite requirement and the 8×8 pattern blocks eliminate the text and multicolor modes, respectively. This leaves only the Graphics I and Graphics II modes, and since two colors per block are all that are necessary, Graphics I is employed due to its ease of use.

Figure 3-2 shows a memory map that allows these functions to fit into a 4K memory area.

Register values for Figure 3-2 are as follows:

- Register 0 — 00 External VDP disabled, M3 = 0
- Register 1 — C0 16K DRAM selected, Blank = 1, Graphics 1 mode selected, SIZE = 0, MAG = 0
- Register 2 — 01 Name Table Start Address @ > 400
- Register 3 — 08 Color Table Start Address @ > 0200
- Register 4 — 01 Pattern Generator Start Address @ > 800
- Register 5 — 02 Sprite Attribute Table Start Address > 100
- Register 6 — 00 Sprite Pattern Generator Start Address @ > 0000
- Register 7 — XX Determined by user.

SPRITE GENERATOR TABLE	0000	32 8 X 8 PATTERNS = 256 BYTES
	00FF	
SPRITE ATTRIBUTE TABLE	0100	32 SPRITES X 4 BYTES = 80 BYTES
	017F	
UNUSED	0180	
	01FF	
COLOR TABLE	0200	32 BYTES
	021F	
UNUSED	0220	
	03FF	
PATTERN NAME TABLE	0400	24 LINES X 32 CHARACTERS = 768 BYTES
	06FF	
UNUSED	0700	
	07FF	
PATTERN GENERATOR SUB-BLOCK	0800	256 PATTERNS X 8 BYTES/PATTERN = 2048 BYTES
	0FFF	

If the same application required 16 x 16 bit sprites, then the memory map could be modified as follows:

SPRITE GENERATOR TABLE	0000	32 16 X 16 SPRITES 32 SPR X 32 BYTES = 1024 BYTES
	03FF	
PATTERN NAME TABLE	0400	24 LINES X 32 CHAR = 768 CHAR
	06FF	
SPRITE ATTRIBUTE TABLE	0700	32 SPRITES X 4 BYTES = 128 BYTES
	073F	
COLOR TABLE	0740	32 BYTES
	075F	
UNUSED	0760	
	0800	
PATTERN GENERATOR SUB-BLOCK		256 PATTERNS X 8 BYTES EACH = 2048 BYTES
	0FFF	

FIGURE 3-2 — VDP-VRAM MEMORY ALLOCATION

3.4 MONITOR INTERFACES

3.4.1 TMS9918A Monitor Interface

The composite video output signal from the TMS9918A drives a color monitor. This signal incorporates all necessary horizontal and vertical synchronization signals as well as luminance and chrominance information. In monitor applications, the requirements of the monitor should be studied to determine if the VDP can be connected directly to it. The internal output buffer device on the composite video pin is a source-follower MOS transistor that requires an external pull-down resistor to V_{SS} as shown in Figure 3-3. Typically a 330-ohm resistor is recommended to provide a 1.9-volt synchronization level. The load resistor (RL) defines the sharpness of the edges on the video signals. A lower resistor value gives faster fall times and a sharper picture.

In some cases, it may be necessary to provide a simple interface circuit to match the VDP output voltages with the monitor specifications. To drive a standard television that is not outfitted with a composite video input, the signal can be run into the television antenna terminals by using an appropriate RF modulator on the VDP output. Take care to ensure a proper match between VDP, RF modulator, and TV.

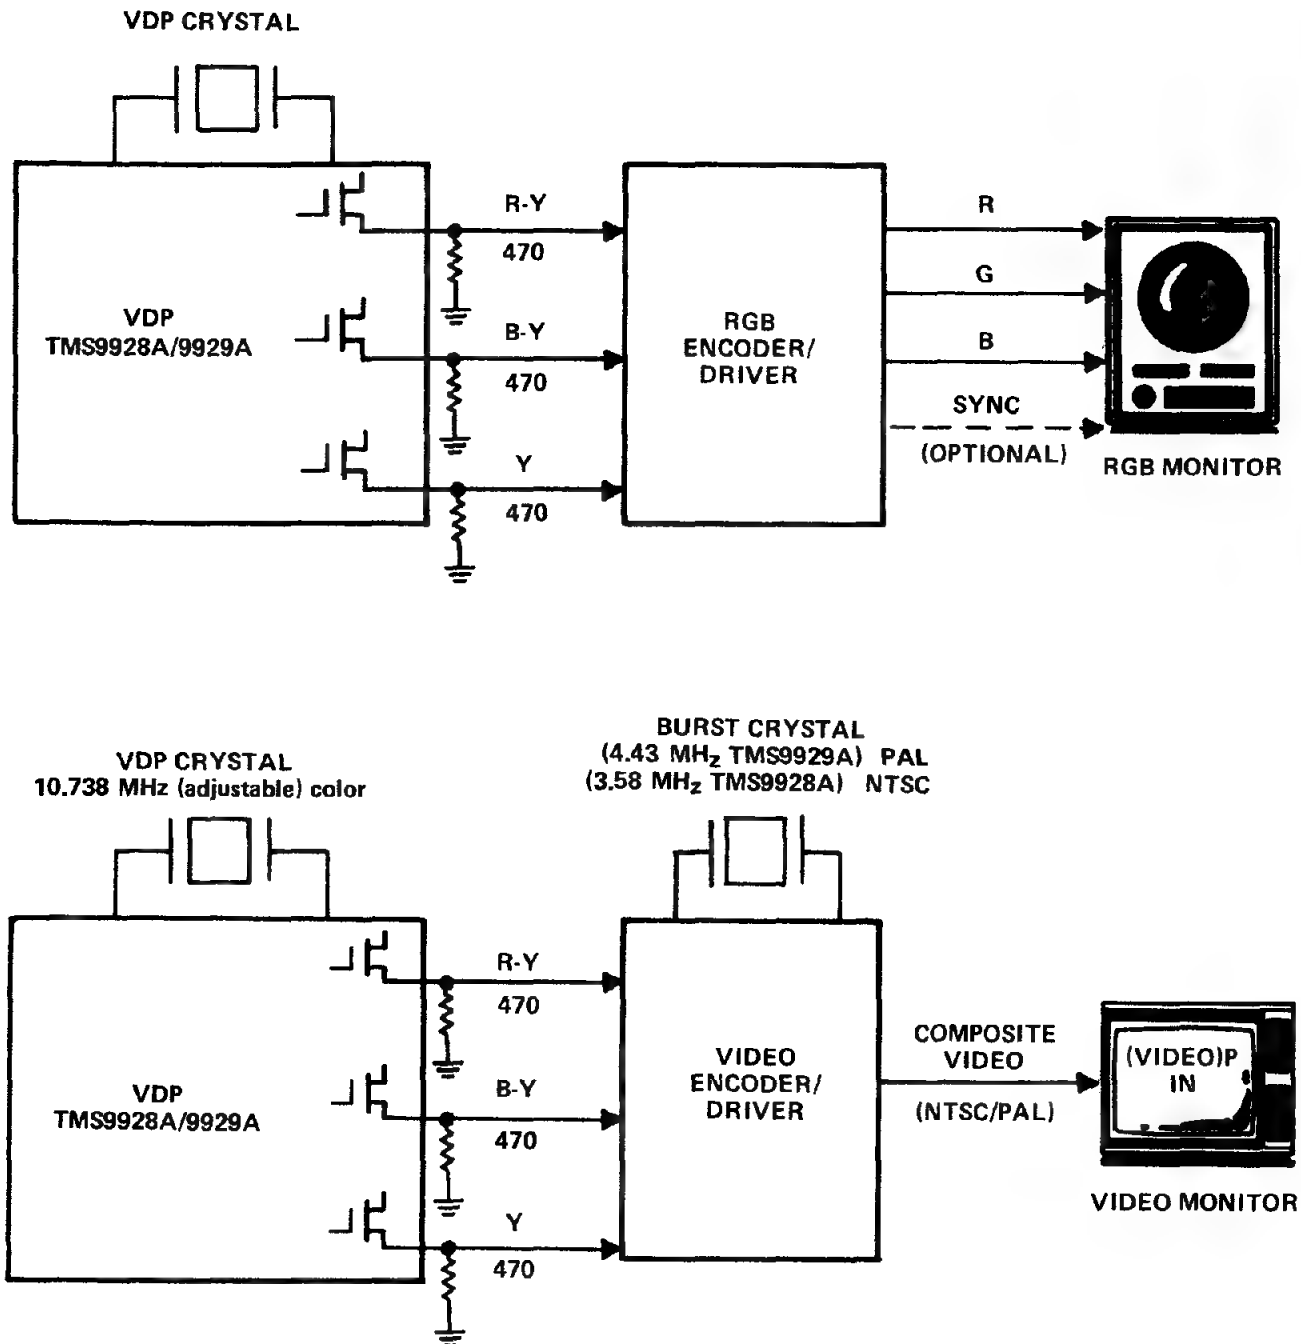

FIGURE 3-3 — COMPOSITE VIDEO PULL-DOWN CIRCUIT

3.4.2 TMS9928A/9929A Monitor Interface

The Y, R-Y and B-Y output signals require external encoder circuitry to drive a video color monitor; an R-G-B matrix circuitry is required to drive R-G-B color monitors. The Y output signal contains all necessary horizontal and vertical synchronization signals as well as luminance while the R-Y and B-Y signals contain the unmodulated chrominance information and are used in the NTSC and PAL systems to modulate two carriers in quadrature. The internal output buffer devices on these pins are source-follower MOS transistors that require an external pull-down resistor to V_{SS} , as shown in Figure 3-4. A 330 ohm resistor is recommended.

NOTE: The LM1889 is typically used in the video encoder circuitry.

FIGURE 3-4 — USE OF TMS9928A/9929A WITH DIFFERENT MONITORS

3.5 TMS9918A EXTERNAL VDP OPERATION

The external VDP interface allows cascading multiple VDPs. Figures 3-5 and 3-6 illustrate cascading two VDPs. Note that the VDPs must be reset by a common reset source to assure synchronization on an open loop basis. This reset source should have fast edges so that rise and fall times are less than 30 ns. Occasionally, synchronization is not obtained after reset, in which case, reset should be reapplied.

The video matching circuit ensures that the video signal of external VDP is biased correctly and of the proper amplitude. This ensures the luminance levels of the external and VDP colors are matched and external VDP video does not bleed through into the composite video output of the first VDP. The internal circuit assures that a perfect match results if the external video is of the same amplitude as the composite video of the VDP and its dc level is increased by a MOS threshold voltage (typically 0.7 volts). This adjustment can be varied to change the relative luminance levels of the two video signals and thus modify the picture appearance.

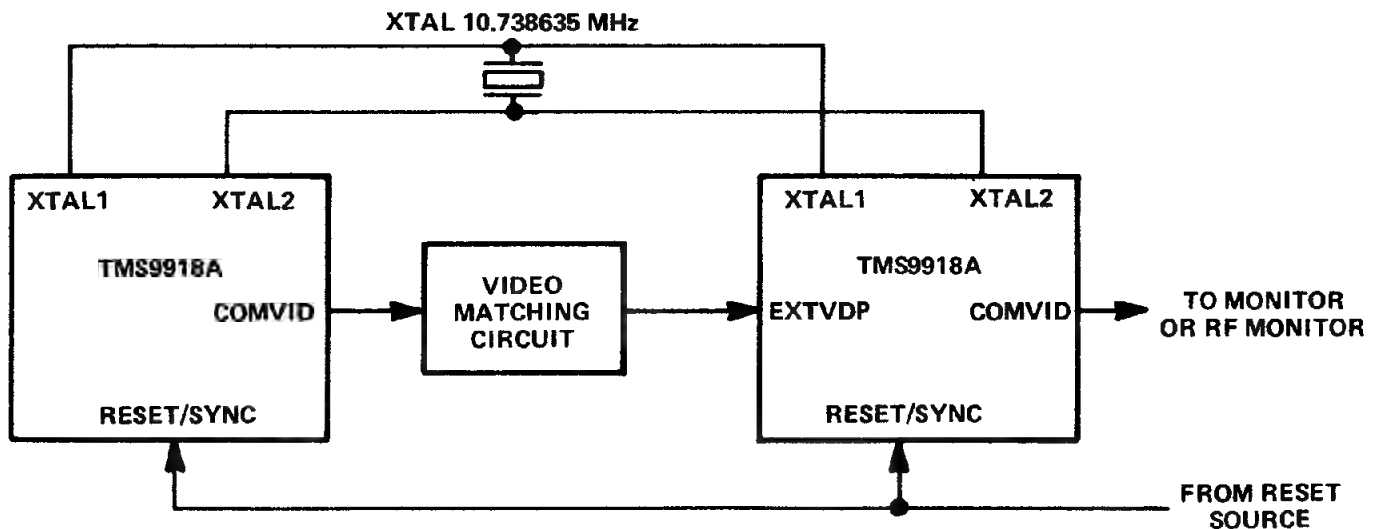

FIGURE 3-5 — CASCADING TWO TMS9918A VDPs

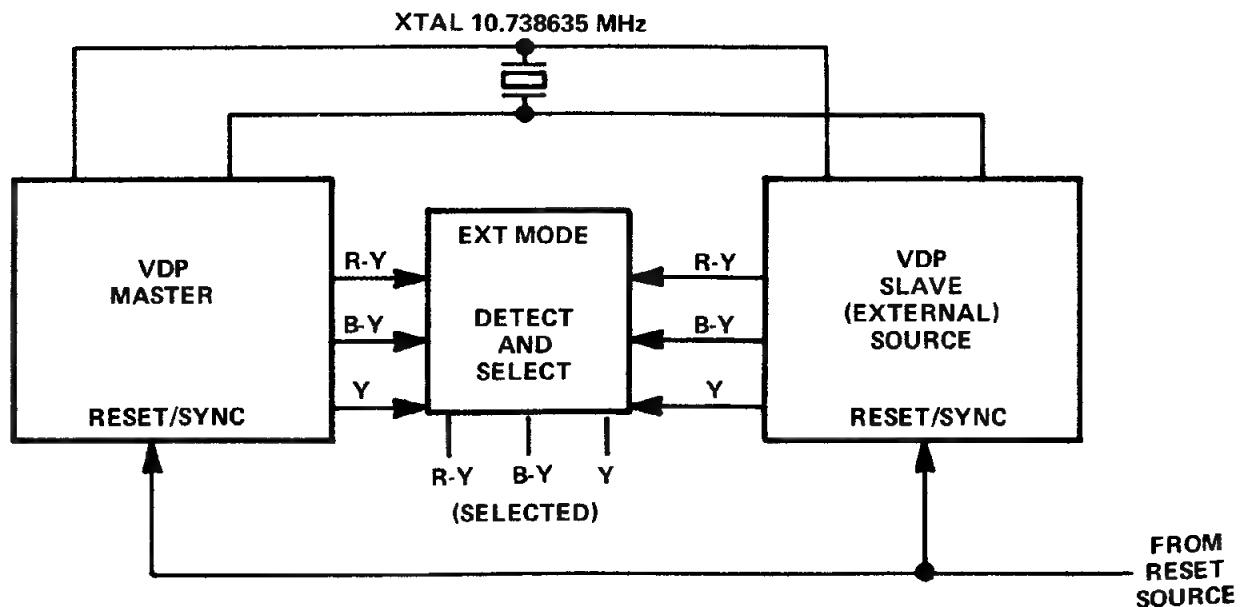

FIGURE 3-6 — CASCADING TWO TMS9918A/9929A VDPs

For the External VDP input plane to be visible, the External VDP Enable bit in VDP Register 0 (EXVID) should be set to a 1. The backdrop color (VDP Register 7, lower 4 bits) should be set to transparent (0). For the external VDP plane to show through at a given spot on the screen, the pattern color at that spot should be transparent, and all sprites should not be in the way (alternatively, a sprite that was in the way could be made transparent in color). Note that the external VDP feature can be used in either Graphics I, Graphics II, Text, or Multicolor mode.

3.6 OSCILLATOR AND CLOCK GENERATION

The VDP is designed to operate with a 10.738635 (± 0.005) MHz crystal input to generate the required internal clock signals. A fundamental-frequency parallel-mode crystal is the frequency reference for the internal clock oscillator, which is the master time base for all system operations. This master clock is divided by two to generate the pixel clock (5.3 MHz) and by three to provide the CPUCLK (3.58 MHz for TMS9918A only). The GROMCLK is developed from the master clock frequency divided by 24 (3.58 MHz for TMS9928A only).

3.6.1 TMS9918A Color Phase Generation

The 10.7 + MHz master clock and its complement generate an internal six-phase 3.579545 MHz (± 10 Hz) clock to provide the video color signals and the color burst reference used in developing the composite video output signal. While the VDP signals are not exact equivalents to the standard NTSC colors, the differences can easily be adjusted with the color and tint controls of the target color monitor.

3.6.2 Video Sync and Control Generation

Decoding the outputs of the horizontal and vertical counters generates the horizontal and vertical control signals. The pixel clock drives the horizontal counter which in turn increments the vertical counter.

Table 3-3 gives the relative count values of the screen display parameters. Within the active display area during Graphics I mode, the three LSBs of the horizontal counter address the individual picture element of each pattern displayed. Also, during the vertical active display period, the three LSBs of the vertical counter address each individual line in the 8×8 patterns. The Graphics II, Multicolor and Text modes use the counters similarly.

The TMS9918A/9929A operates at 262 lines per frame and approximately 60 frames per second in a noninterlaced mode of operation. The TMS9929A operates at 313 lines per frame and approximately 50 frames per second in a noninterlaced mode of operation.

4. DEVICE APPLICATIONS

This section describes the hardware and software interface between a TMS9918A/9928A/9929A VDP and a TMS9900 microprocessor. Some considerations in the use of the VDP for text and graphics applications are also described.

4.1 VDP TO TMS9900 INTERFACE

The circuit shown in Figure 4-1 illustrates a very simple interface between a TMS9900 microprocessor and a TMS9918A/9928A/9929A. In this circuit, the VDP 8-bit data bus is connected to the 8 MSBs of the TMS9900 16-bit data bus. For mode selection, A14 of the TMS9900 is connected to the mode input pin. Read and write signals to the VDP are as follows:

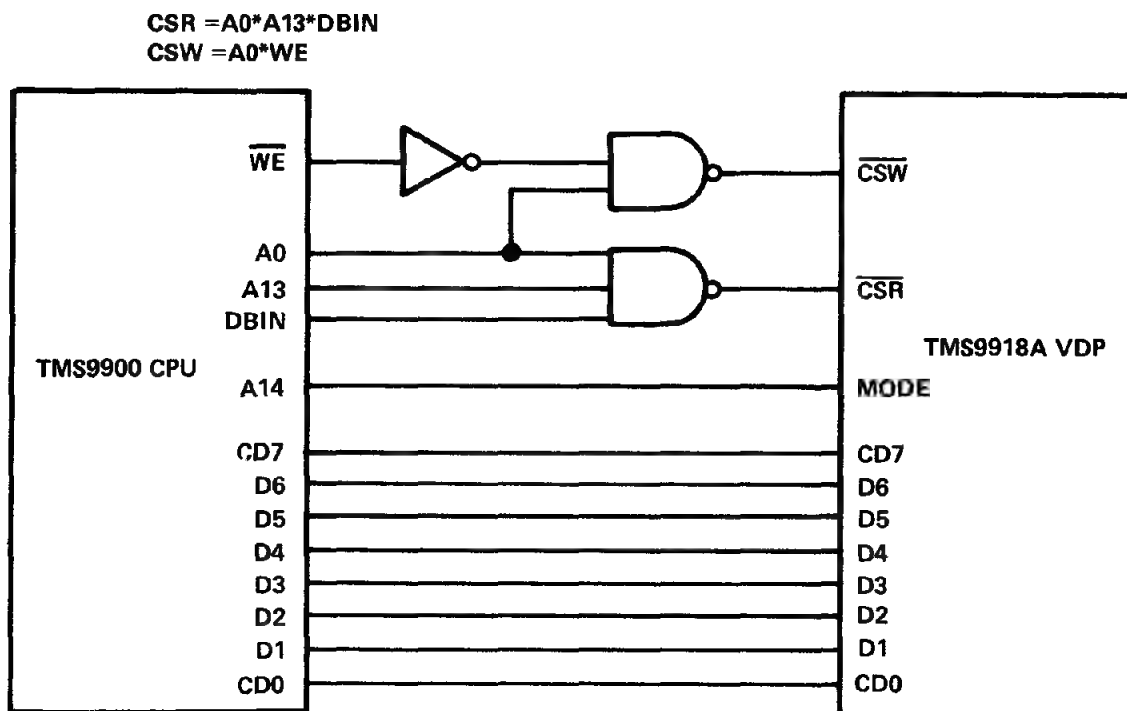

FIGURE 4-1 — MINIMUM SYSTEM INTERFACE TO TMS9900

DBIN and $\overline{\text{WE}}$ are signals from the TMS9900 which indicate direction flow on the data bus. DBIN is high when the CPU is attempting to do a read data operation, while $\overline{\text{WE}}$ is low when the CPU is outputting data onto the data bus.

A0 is used as a VDP select signal. Thus, the VDP is activated whenever the CPU is reading or writing data in the upper half of its address space (> 8000 and above). All addresses above > 8000 then become VDP port addresses. However, in a more sophisticated design, more decoding of the address lines would be done to select only those unique addresses required by the VDP. The purpose of A13 and decoding logic is to generate unique addresses for read and write operations and to block out the read data operation that occurs on the TMS9900 before a write data operation. Without this blockout logic, a pulse on the CSR input would occur before any desired pulsing of the CSW input, thus causing unwanted operation of the VDP. Referring to Table 4-1 and Figure 4-1, the following port addresses can be defined.

TABLE 4-1 — VDP PORT ADDRESSES FOR FIGURE 4-1

OPERATION	$\overline{\text{CSW}}$	$\overline{\text{CSR}}$	MODE	PORT
Write data to VRAM	0	1	0	>8000
Write address to VRAM or Write to VDP register	0	1	1	>8002
Read data from VRAM	1	0	0	>8004
Read VDP status	1	0	1	>8006

4.2 TMS9918A/9928A/9929A INTERFACE

Figures 4-2 and 4-3 show the hardware components necessary to make the VDP operate with a typical TM990 16-bit bus application. The CPU can be connected as shown to any general-purpose 8-bit data bus and control signals that work with most microprocessors. The VDP interface timing is similar to that of static memories and occupies eight unique memory address locations within the CPU memory address space.

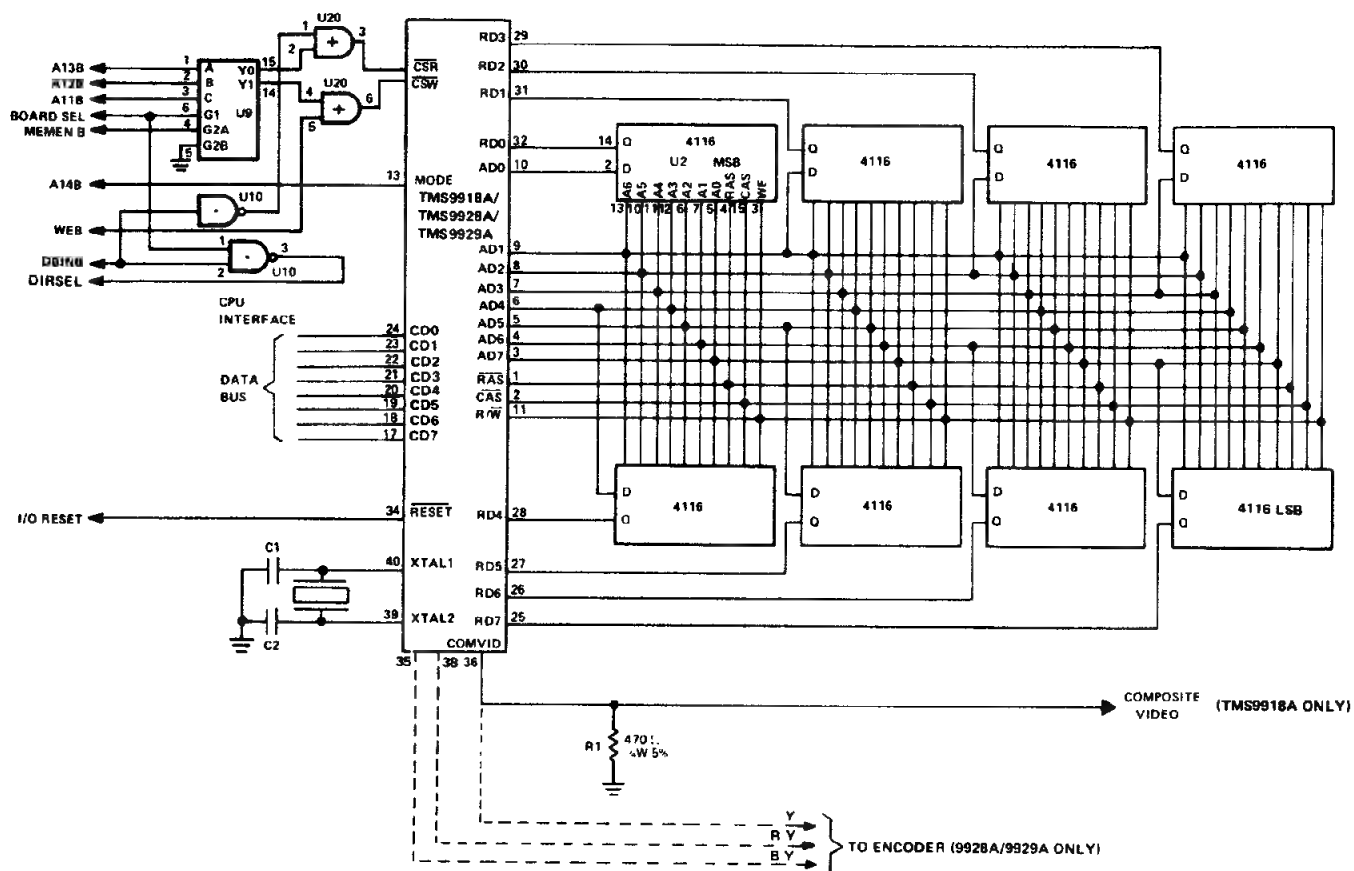

FIGURE 4-2 — TMS9918A/9928A/9929A INTERFACE

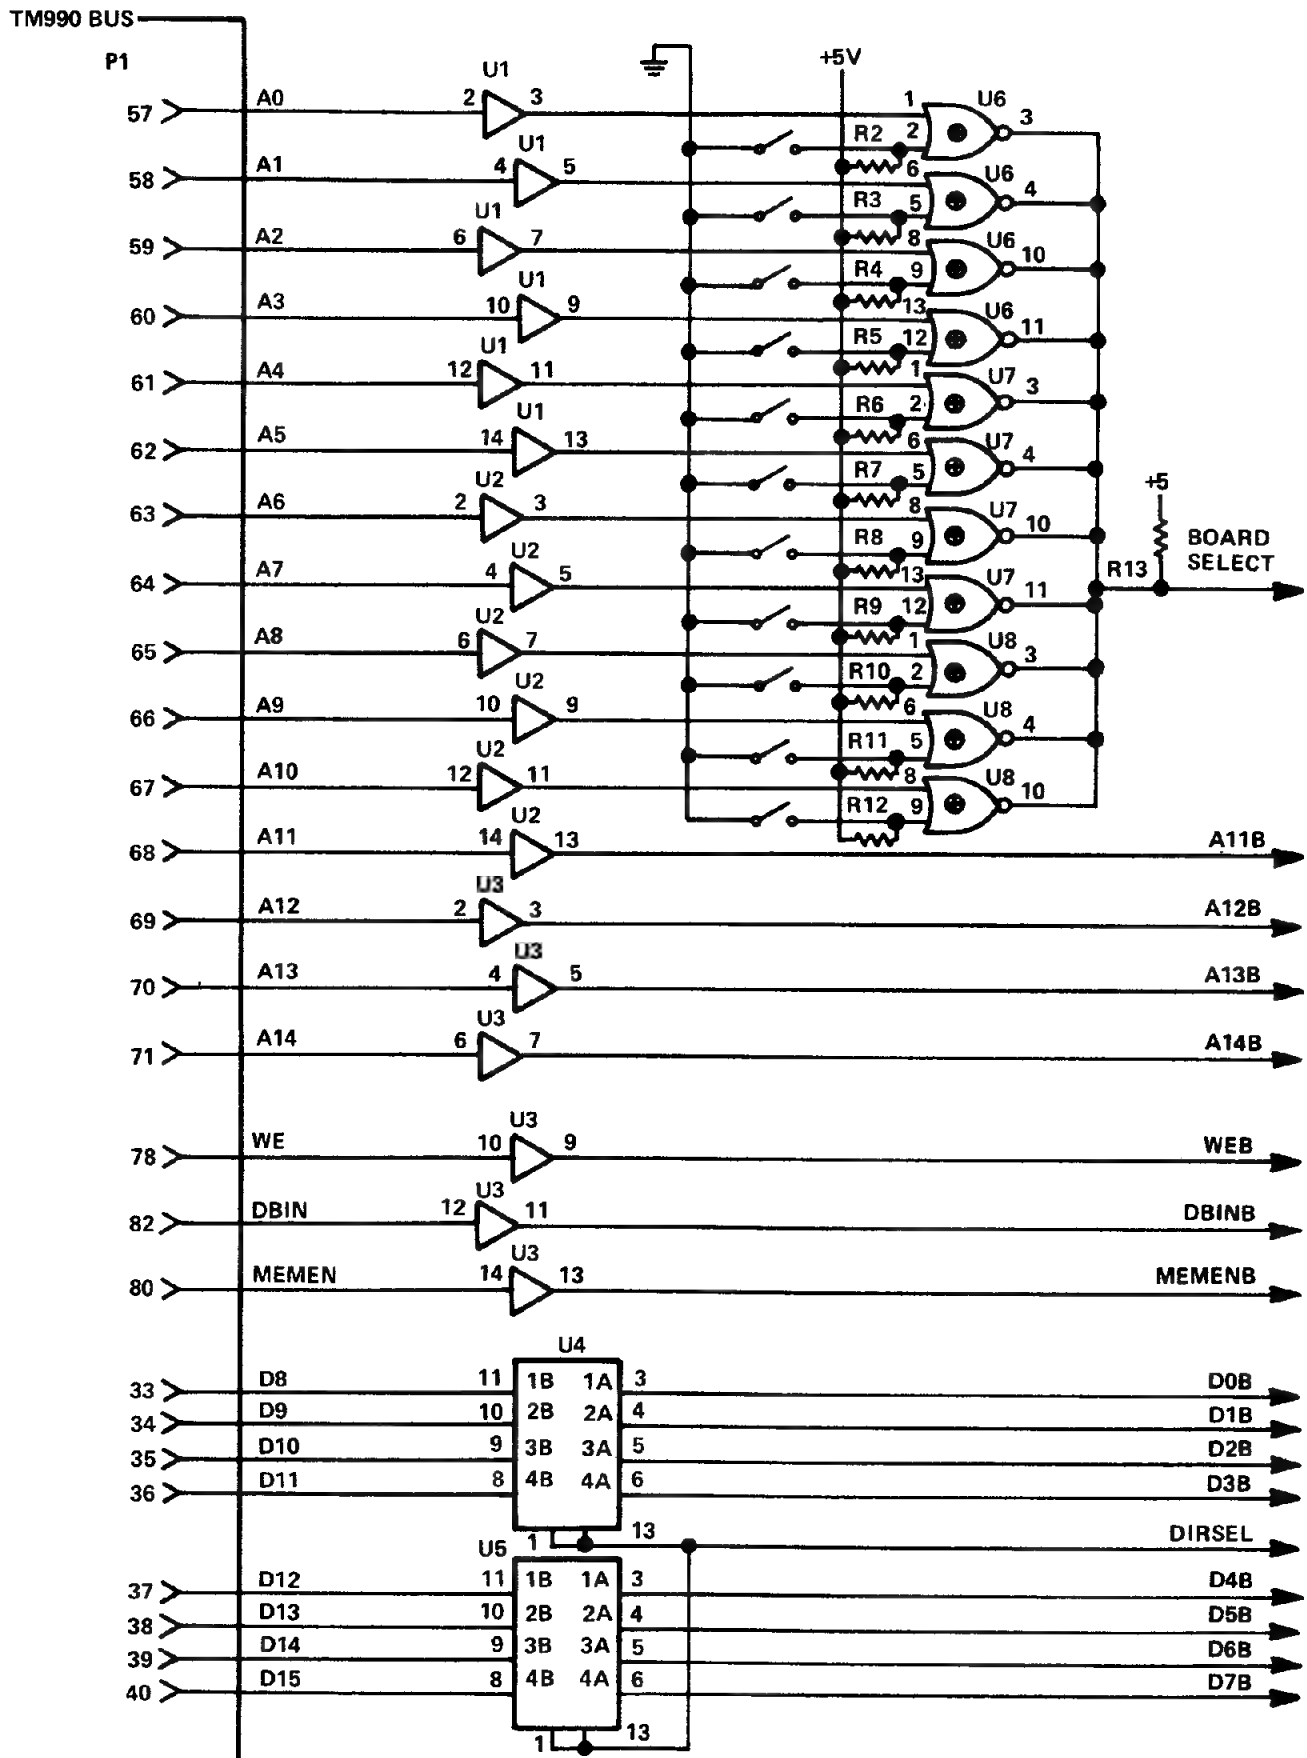

FIGURE 4-3 — TM990 (TMS9918A/9928A/9929A) DEMO BOARD

SW1-3	4-position DIP Switches
R1	470 Ω 5% 1/4 W
R2-R13	Bourns XXXX or equivalent

NOTE: All power supply pins of each IC should be bypassed with a .1 μ F capacitor.

4.2.2 Composite Video Output

The TMS9918A composite video output pin (36), is driven by a source-follower MOS transistor that requires an external pull-down resistor to V_{SS} . A 470-ohm resistor is typically used to provide a 1.9 volt peak-to-peak signal on the output. This output will drive most color directly, although in some cases it may be necessary to provide a simple interface circuit to match the monitor's input requirements. If a color video monitor is not available, an RF modulator can be used to drive the antenna terminals of a standard color television, as shown in Figure 4-4.

FIGURE 4-4 — RF MODULATOR CONNECTION

4.2.3 Oscillator and Timing

The TMS9918A/9928A/9929A internal timing generation is controlled by a self-contained oscillator and timing circuits. A 10.738635 ($\pm 0.005\%$) MHz fundamental-frequency parallel-mode crystal is used to drive the basic oscillator frequency.

C1 and C2 are load capacitors for the parallel-resonant crystal. C1 and C2 values may be varied slightly to obtain more accuracy in timing and color generation and also to compensate for stray capacitance on the PC board. Typical values for C1 and C2 range between 15 pF and 39 pF. A trimmer capacitor with a value of 5 pF to 50 pF may also be used instead of C1 and adjusted to provide proper colors to the video monitor.

The VDP may also be operated with an external oscillator source. The VDP connections for this external source are shown in Figure 4-5.

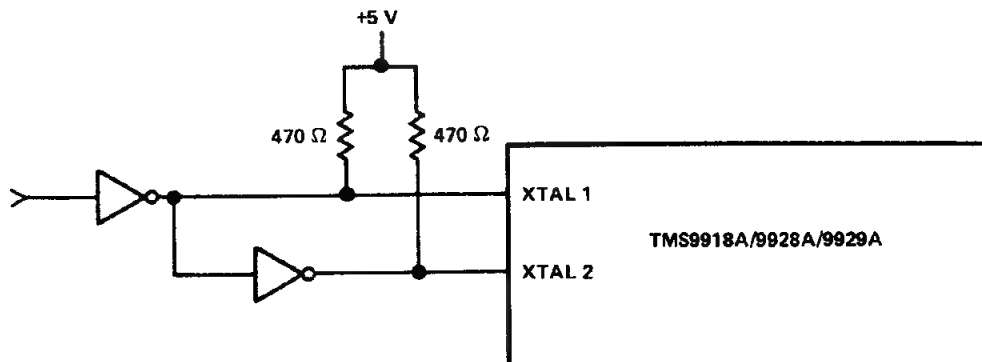

FIGURE 4-5 — EXTERNAL FREQUENCY SOURCE

There may be a slight color shift or a complete color loss in applications of RF modulators if there are mismatches in voltages levels or impedances between the VDP and the RF modulator. See Figure 3-4 for the TMS9928A/9929A interface.

4.2.4 VRAM Connections

The VRAM used in Figure 4-2 are 4116-type dynamic RAMs that meet the specifications in Section 5.

Addressing of the VRAM is done through the address bus and the memory control lines, AD1-AD7 and RAS, CAS, and WR, respectively.

Data written to the VRAM is also sent over the address bus. AD0 is a MSB, and AD7 is the LSB. Data written from the VRAM is brought into the VDP via the read data bus, RD0-RD7. The TMS9918A automatically refreshes the VRAM with no interaction necessary from the host CPU.

Note that address 0 (AD0) and data 0 (D0) are the MSBs for the TMS9918A and all other TMS9900 family members. The VRAM pin designations (A0 and D0) referenced in the data manual are shown as being the LSBs to be consistent with 4116-type dynamic RAM data sheets.

4.3 VDP INITIALIZATION

After powerup and proper reset timing, the VRAM allocation backdrop color and type of dynamic RAM need to be loaded into the VDP registers.

The values to be loaded can be calculated by using the examples and tables shown in Appendix A. The following flowchart (Figure 4-6) shows a procedure for loading all eight VDP registers. Setting 4.4 contains a typical TMS9900 software program designed to work on the demo board, shown in Figure 4-3.

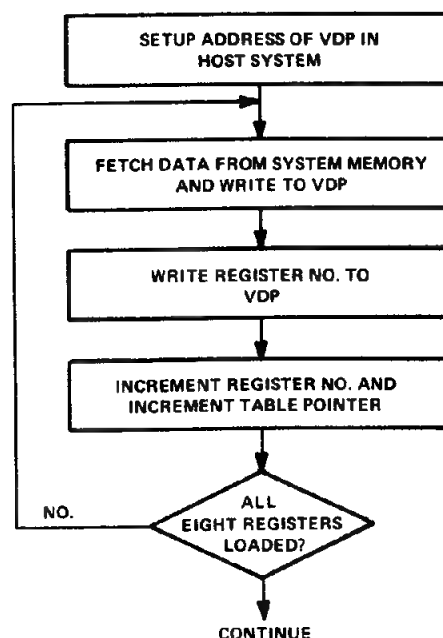

FIGURE 4-6 — VDP REGISTER INITIALIZATION PROCEDURE

4.4 TYPICAL SOFTWARE PROGRAM

4.4.1 General

This program initializes the TMS9918A and loads the Pattern Generator with the upper case character set. It then loads the color table, clears the screen and prints a sign-on message. After initialization, a user program address can be inserted at location 00A4.

5. TMS9918A/9928A/9929A ELECTRICAL SPECIFICATIONS

5.1 ABSOLUTE MAXIMUM RATINGS OVER OPERATING FREE-AIR TEMPERATURE RANGE

(unless otherwise noted)*

Supply voltage, V_{CC}	– 0.3 to 20 V
All input voltages	– 0.3 to 20 V
Output voltage	– 2 to 7 V
Continuous power dissipation	1.3 W
Operating free-air temperature range	0°C to 70°C
Storage temperature range	– 55°C to + 150°C

*Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the Recommended Operating Conditions section of this specification is not implied. Exposure to absolute maximum rated conditions for extended periods may affect device reliability.

5.2 RECOMMENDED OPERATING CONDITIONS*

PARAMETER		MIN	NOM	MAX	UNIT
Supply voltage, V_{CC}		4.75		5.25	V
Supply voltage, V_{SS}			0		V
Input Voltage, V_I , $\overline{\text{RESET}}/\text{SYNC}$ pin	SYNC active	10		12	V
	RESET active			0.6	V
	SYNC and RESET inactive	3		6	V
High-level input, V_{IH}	XTAL1, XTAL2	2.75			V
	All other inputs	2.2			V
Input voltage, V_I , EXT VDP pin (TMS9918A only)	SYNC level		2.6		V
	White level		3.7		V
	Black level		3		V
Low-level input voltage, V_{IL}				0.8	V
Operating free-air temperature, T_A		0		70	°C

* All voltage values are with respect to V_{SS} .

5.3 ELECTRICAL CHARACTERISTICS OVER FULL RANGES OF RECOMMENDED OPERATING CONDITIONS
(unless otherwise noted)

TMS9918A/9928A/9929A

PARAMETER			TEST CONDITIONS	MIN	TYP†	MAX	UNIT
V _{OH}	High-level	RAS, CAS, R/W	I _{OH} = 400 µA	2.7	3.4		V

APPENDIX A

ASCII CHARACTER SET

Software programs apply to all three VDPs (TMS9918A/9928A/9929A).

This appendix contains the diagrams and software listing of an upper and lower case ASCII character set. The character matrix is 5 X 7 in the 8 X 8 pixel block. These characters are left-justified so they can be used in the text (6 X 8 pixels) mode.

APPENDIX B

CHOOSING VRAM MEMORY

When choosing the VRAM memory, the user must take into consideration the propagation delay times of the system in addition to the access time of the memory and data setup time of the VDP.

After the VDP outputs a low level signal on $\overline{\text{RAS}}$, there is a delay time ($t_{d(\text{RAS})}$) for this low level to reach the VRAM memory; there is a similar delay ($t_{d(\text{CAS})}$) for a signal output on the $\overline{\text{CAS}}$ pin to reach the VRAM memory. Finally, there is a delay ($t_{d(\text{data})}$) for data output by the memory to reach the VDP. These delays (shown in Figure B1) depend on the length of the wires between VDP and memory, and on the capacitive load being driven.

Valid data appearing on RD0-RD7 is strobed into the VDP when $\overline{\text{CAS}}$ is brought high. Therefore, the memory chosen must have fast enough access times, $t_{a(\text{R})}$ and $t_{a(\text{C})}$, so that valid data is present on RD0-RD7 when a positive transition occurs on $\overline{\text{CAS}}$.

For 16-K memories from Texas Instruments (TMS4116-XX), the times, $t_{\text{RL-CL}}$ and $t_{a(\text{C})}$, can vary, but their sum is equal to $t_{a(\text{R})}$ ($t_{\text{RL-CL}} + t_{a(\text{C})} = t_{a(\text{R})}$). Thus, when $t_{d(\text{RAS})} \geq t_{d(\text{CAS})}$, the limiting access time is $t_{a(\text{R})}$.

After the memory receives a negative transition on the $\overline{\text{RAS}}$ input, the memory access time, $t_{a(\text{R})}$, must be fast enough so that valid data is present on RD0-RD7 when $\overline{\text{CAS}}$ goes high (see Figure B2). The equation for this is:

$$t_{\text{RL-CL}} + t_{\text{wCL}} \geq t_{d(\text{R})} + t_{d(\text{data})} + t_{\text{su}(\text{D-CH})}$$

Under worst case conditions, this equation can be used to find out how much time is allowed for system delays using different memories.

TABLE B-1 — WORST CASE TIMING FOR VDP.

MEMORIES	SYSTEM DELAYS
t_{wCL}	230 ns MIN
$t_{\text{RL-CL}}$	40 ns MIN
$t_{\text{su}(\text{D-CH})}$	60 ns MAX

If the values from Table B1 are placed in the equation, we find ($t_{\text{RL-CL}} + t_{\text{wCL}}$) VDP MIN \geq [$t_{d(\text{RAS})} + t_{d(\text{data})}$] SYS + $t_{a(\text{R})}$ MEM + $t_{\text{su}(\text{D-CH})}$ VDP MAX]

$$210 \text{ ns} - t_{a(\text{R})} \text{ MEM MAX} \geq [t_{d(\text{RAS})} + t_{d(\text{data})}] \text{ SYS MAX}$$

TABLE B-2 — DRAM SYSTEM DELAYS

PART NO.	$t_{a(\text{R})}$	SYSTEM DELAYS
4116-15	150 ns	60 ns MAX
4116-20	200 ns	10 ns MAX
4116-25	250 ns	-40 ns MAX

From the data given here, the VDP will work with both -15 and -20 TMS4116 dynamic RAMs provided the system delays are small enough. The VDP does not meet the $t_{a(\text{R})}$ specifications for the -25 TMS4116 and is unable to use the -25 under worst case conditions. The VDP has been verified to work with both -15 and -20 TMS4116s in a system application. Note that in addition to the equation derived above, that all memory timing requirements must be met as specified in a memory data book.
